Case 5.—Baby S., first baby, father a physician. Weight at birth 6½ pounds. Vomited every feeding. Bowels green and curded; anus excoriated. Mother very nervous. Diagnosis of probable pyloric obstruction made and advisability of weaning was being considered. Mother reassured. Pyloric obstruction eliminated. Milk contained high fat percentage. Mother dieted and purged. Told to ignore digestive symptoms. Small dose of strontium bromid and a little water administered before feeding. Baby continued to gain in spite of digestive symptoms, which gradually subsided. Present weight at six weeks, 10 pounds. Usual course in this case would have been to wean, with probable disaster on account of the approach of summer.

Case 6.—Baby G., first infant. Mother well. Father a physician. Infant cried a great deal. Mother therefore convinced that she did not have enough milk and infant was starving. Very difficult to control. Finally *convinced* by actual weighing experiments before and after feeding and the progressive gain in weight.

Case 7.—Baby L., father a physician. Had lost one infant from summer-complaint on bottle. Mother during puerperium had received an ounce of Epsom salt a day and besides had inverted nipples and small breasts. Rose from childbed weak, anemic and with flabby breasts. Flow appeared about to be leaving. Regular nursing advised, forced feeding, with *oatmeal* and Southworth's soup.[1] Return of flow was gradual and the gain in weight tedious. I refused to wean on account of summer. Mother very nervous. Both parents, against their better judgment, frequently threatened to give artificial food. Flow finally established. Result: a fat, healthy babe.

Case 8.—Mrs. W., mother of two children. Very stout. Breast well developed, but not so much glandular substance. Confined with present baby in hospital. Permitted to get up on ninth day and to leave hospital on tenth day. Result: severe uterine hemorrhage. Rest in bed and forced feeding only partially restored flow of milk. Finally had to wean in summer. Result: severe intestinal disturbances. Final recovery. Remarks: Fault lay with the accoucheur. All trouble could have been avoided.

Thus, in a general way an attempt has been made to state the influences at work which have been responsible for the decadence of the habit of breast-feeding, and it would seem from my experience that the following conclusions are justifiable:

## CONCLUSIONS

1. Breast-feeding is the only sane and safe method of infant-feeding.

2. The breast is too frequently sacrificed without cause.

---

[1] Southworth's soup consists of 2 tablespoonfuls of yellow corn-meal boiled one-half hour with 1 quart of water. Water of evaporation is made up by addition of hot water. Whole is salted and flavored to taste. About 1 quart a day is drunk.

3. Psychic influences are largely determinable so far as the mother is concerned.

4. Fear plays an important rôle in the etiology of artificial feeding.

5. The two most common examples of fear depend on the mother's belief in her inability to provide suitable nourishment and on the signs of early indigestion which are erroneously regarded as a contra-indication to the continuance of breast-feeding.

6. The profession of the country has not been sufficiently educated in the methods of dealing with nutritional and digestive disturbances of the breast-fed.

7. Medical curriculums are lacking in such instruction.

8. Too much time has been spent in studying the problems of artificial nourishment without very much progress or benefit.

9. Physicians resort too quickly to artificial feeding.

10. Economic and social reasons for discontinuing the breast are the most difficult to overcome and find their origin in the present social system.

11. Charity is but a makeshift to relieve the present state of error. It is unnecessary and not humane.

12. A mutation of economic and social conditions, while offering relief, is remote.

13. In the interim nursing mothers should receive actual cash compensation from the state.

14. A campaign of education directed toward legislators, mothers and physicians is urgently needed and should be undertaken by the Section on Diseases of Children of the American Medical Association and the pediatric sections of allied organizations.

*1927 North Broad Street.*

## ABSTRACT OF DISCUSSION

Dr. John Zahorsky, St. Louis: Most writers on the subject seem to agree that there are few mothers who are unable to nurse their babies. As an actual fact, I have great difficulty in private practice in keeping many babies on the breast, and I do not think that we can be as optimistic as Dr. Lowenburg that we can do this. I am excluding now any mother who has not enough to eat. I mean mothers of the better class who can pay for the best food and the best care. Many of them cannot nurse their babies in spite of all the psychotherapy that I can give and all the feeding methods that I can devise. The usual symptoms are acute indigestion and the baby does not thrive. The mother nurses the baby according to the ordinary rule. Nevertheless the baby does not thrive; it has severe dyspeptic symptoms that are not improved by lengthening the interval between feedings. What shall we do with these babies? They are very numerous. I have not been successful with these cases, and do not know anyone who has. I am collecting records of a large number of these cases which I hope some time to present. These babies are usually fed by supplemental or complemental feedings, and the mother soon finds that the baby does better, likes the artificial food better than the breast, and then she gives it more in spite of the doctor's advice. Why the mother's milk does not agree with the child we do not know.

When a mother asks my advice about putting her baby on the bottle, I say to her, "If you were going to have an operation performed on your baby in which there was a mortality of from 10 to 15 per cent. would you not consult several physicians before having to undergo the operation?" I then suggest that she consult two or three physicians before putting the baby on the bottle, since this has an equal mortality with an operation. We generally succeed in keeping these mothers from weaning the babies, but that does not always mean that the babies are fed.

Dr. C. F. Wahrer, Fort Madison, Iowa: I do not believe that a certain class of Dr. Zahorsky's patients come under Dr. Lowenburg's classification. I want to make a plea for those mothers who want to nurse their babies and can do it, but for some reason have been ignorantly advised. Within the last six months I confined two sisters about three and a half months apart. They both had a "Sary Gamp" for a nurse. She told the first sister that she could not nurse her baby because the milk was too thin. A few days after my last attendance the husband came to me and said the wife's breasts were hard and large. I said, "Have you been removing the milk?" He said, "Yes," I said, "What did you do with the milk?" He said, "Threw it away." I said, "What do you feed the baby on?" He said, "The bottle." Now in such a case the doctor must make his moral influence felt. I told him that they must feed this baby on its mother's milk or do without my services. If patients want to follow the advice of "Sary Gamp," who maintains that she has raised thirteen children and for that reason should give advice (although she has lost seven of them), they can do without my services. I told this nurse that she must not interfere any more or I would show her the door.

The same thing occurred when the second sister was confined. They also had "Sary Gamp." I told the mother that if she did not nurse the baby I would not come to the house again. Both these mothers are nursing their babies and are happy.

Dr. H. D. Chapin, New York: There seems to be some difference of opinion. There are some women who do wish to nurse their babies, but are physically unable to do so, although they are willing to follow all the directions that are given them.

Dr. H. W. Francis, Bancroft, Neb.: I live in a small town. I seldom have trouble in getting the mothers to nurse their babies. Occasionally we have a mother whose milk does not seem to agree with the baby. In my experience, the continued use of sodium citrate given to the baby at nursing time is often beneficial. I have continued this as long as three months without any harmful effect and it proves of benefit to the baby. It stops the colicky spells.

Dr. L. R. DeBuys, New Orleans: There is one thing that Dr. Lowenburg may have forgotten to mention which I think should be emphasized, namely, the care of the breast and the care of the nipples before confinement. It is absolutely essential. I recently saw a mother who was extremely anxious to nurse her baby. The baby was 11 days old. It was torture for her to try to nurse him, her nipples were so fissured. In a few days under the proper management the nipples were healed and she resumed nursing her baby without any pain or inconvenience. It is essential to have good nipples in order to have mental rest and effectual encouragement.

We meet two classes of mothers, those who want to nurse their babies and cannot, and those who do not want to and can. In the case of the latter I think that we are perfectly right in taking the position that Dr. Wahrer has taken. In those cases in which the mother wants to nurse her baby and cannot, my practice has been, if she is supplying a little milk which is not causing any digestive disturbance, to weigh the baby before and after nursing to determine what the baby is getting and make complemental feedings to meet the requirements. I have frequently found that the mother can nurse the baby for six or seven months in this way.

In an instance in which the mother was giving 4 ounces in twenty-four hours, by this method, in the course of three months she was giving 20 ounces of milk; the baby, of course, was having complemental feedings. Incidentally, the mothers in these cases were in good circumstances.

There is a tendency to wean the baby if the stools are not perfect, that is, are not normal custard stools. We must remember, in this connection, that it takes some weeks, two or three, sometimes a month, for the baby to become adapted to the breast and the breast to the baby.

I have had a rather unique experience in connection with an abscess of the breast. The breast had to be operated on. I allowed the baby to continue to nurse the healthy breast; and during the period when the diseased breast was being treated surgically I used puppies to nurse it, and in this way kept the breast functionating. After the breast had entirely healed and there were no organisms in the milk, the baby was put back to that breast, which continued to functionate satisfactorily.

Dr. Collins H. Johnston, Grand Rapids, Mich.: I have not found many mothers who do not wish to nurse their babies. Many mothers have not been taught that the mortality of bottle-fed babies is eight or ten times that of breast-fed babies. In my lectures to nurses I always emphasize the fact that there are but two contra-indications on the mother's part to nursing a baby. One is advanced heart disease, the other pulmonary tuberculosis. There are, of course, other occasional conditions in which we may, if necessary, advise weaning, but these two classifications will cover the great majority of cases.

I think also that physicians are frequently too careless in permitting mothers to wean their babies. We do not always sufficiently realize the difference, not only in the first year of life, but in later years, between breast-fed and bottle-fed babies. We all know that the death-rate among bottle-fed babies in the first year of life is much greater than among breast-fed babies, but we do not all realize the great influence breast-feeding has on the growth and development of children in the first five or ten years of life.

I saw some interesting statistics pertaining to this at the International Hygiene Exhibition in Dresden two years ago. In twenty-four families with one hundred and nine children, all breast-fed, at the end of at least five years of married life, not one of the children had died, while every one of the thirty-three families in which babies were all bottle-fed had lost one or more children during the same period.

Especially interesting were the results in families in which some of the children were breast-fed and some bottle-fed. In seventy-nine families of this class investigated there was a group of twenty-nine families with eighty-five breast-fed and one hundred and nine bottle-fed babies. At the end of eleven years all of the breast-fed children were alive and 57 per cent. of the bottle-fed babies were dead. In another group of thirteen families with forty-eight breast-fed and twenty-three bottle-fed babies, at the end of ten years all of the breast-fed babies were alive and all of the bottle-fed babies were dead.

We must not lose sight of these results of breast-feeding in infancy. The two main periods in which mothers wean their babies before the natural time for doing so are in the first month and in the fourth or fifth. The causes of weaning in the first month are vomiting, diarrhea, etc.

I often tell mothers that I do not care how many stools the baby has in the first month of life, whether one or two or twenty a day, nor how much the baby cries, provided it gains in weight. It frequently takes several weeks for a baby's stomach to adjust itself to mother's milk and during this time more or less gastro-intestinal trouble is bound to result. If the mother concludes that this is due to some imperfection in her milk and weans her baby on this account, a great mistake is made. I believe that the occasions when a baby should be weaned on account of some fault in the mother's milk are rare. When, after a thorough trial, it is found that a baby will not thrive on breast-milk, the fault is usually with the baby and not with the mother.

Dr. Frank C. Neff, Kansas City, Mo.: I think that Dr. Lowenburg's criticism of the medical profession is well founded in many ways. It does not apply, however, to men who are practicing pediatrics.

A custom which I have followed, and which I understand from Dr. Smith is followed in Boston, is to secure the breast-milk whenever it can be obtained from healthy women. Often the mother is willing to nurse the baby, but she thinks that she has not enough milk and does not know what else to do but give it the bottle. In this case, it is my practice to give supplemental feedings: to find out how much the baby is getting by weighing it before and after nursing and then to get supplemental milk from relatives or friends or any healthy mother who has more milk than she needs. When this milk is not procurable in any other way I have resorted to advertising in the daily paper, offering to pay a healthy mother so much a week for so many ounces of milk, she to come to the house as often as necessary and have the milk drawn out to be kept on ice and used subsequent to each nursing—not to take the place of any nursing. The baby should be nursed at the breast as much as possible and then fed this breast-milk from the bottle. I should like to ask you to try this method. It is surprising what a small amount of breast-milk some babies thrive on. This will solve many problems in cases in which the milk is insufficient for complete feeding.

Dr. E. O. Benson, Chicago: In the great majority of cases, there is no difficulty in inducing the mother to nurse the baby. In fact, the great majority of mothers among the better classes are anxious to nurse their babies. They have heard that there is a large proportion of mothers who cannot nurse their babies, and they are afraid that they may be in that class.

Years ago, when percentage feeding was first introduced, it was thought that a panacea had been found, but experience has taught us that there is no substitute for mother's milk, and this knowledge has come to the reading laity. As Dr. Gengenbach mentions, the nursing possibilities of women are influenced by their mental emotions and by artificial surroundings. A large proportion of women among the poorer classes take it for granted that they should nurse their babies. They have nothing else to think of but the care of their houses, their husbands and babies. Some mothers have difficulty because they are underfed, others because they are overfed. We must avoid too rich food as well as too poor food. In certain rural communities in the old country, in which mothers eat sour milk, old bread and little butter, possibly meat once a week, and otherwise subsist on cereals and gruels, you will find a large proportion of healthy babies and a large proportion of mothers who are able to nurse their babies.

I do not believe that physicians are such great sinners as Dr. Lowenburg seems to intimate, but we must put this matter strongly to physicians in order that they may advise every mother to nurse her baby.

Some babies, even after the best efforts, must be put on artificial feeding. Dr. Lowenburg rather condemned the time spent in studying artificial feeding, but many babies come to us after they have been weaned without the advice of a physician. When we leave a case, after confinement for example, we tell the mother to come to us when the baby is in difficulty. She does not do it. She first takes the advice of the neighbors or the grandmother, and then, after the child's digestion has been damaged by experiment, she comes to the physician and he has to meet the problem of artificial feeding. The number of these cases is large and the physician is not responsible for them.

Dr. H. Lowenburg, Philadelphia: My experience does not permit me to agree with Dr. Zahorsky as to the inability of many mothers to nurse their babies, nor with the importance he places on the occurrence of dyspepsia in breast-fed babies. Possibly I meet just as many cases of indigestion and green stools in the breast-fed as he does, but I have come to regard them as of no importance and pay absolutely no attention to them. I meet green stools, curds and colicky babies, but, if the child continues to gain in weight—you will find that most of them do—I think that we should pay no attention to the character of the stools at all. I believe that from the cradle up infants require a little wholesome neglect. I think that they should not be fussed over too much. I think that we should pay less attention to the importance of dyspepsia in the breast-fed and think that all women with mammary glands can nurse. The patients that come under our observation who will not be able to nurse their babies will then become fewer in number. I do not say that women are not willing to nurse, but I *do* say that many of them are actuated by fear that they cannot, or that their milk does not agree with the child. It is important, as Dr. Zahorsky suggests, to make a systematic study of the stools of the breast-fed, to learn, if possible, just why it is that these infants do have green movements, because I believe that almost every one of them does.

It is important that the breasts should receive attention during the whole puerperium. Every other physical defect of the mother should be noted and corrected as well.

Dr. Wahrer mentioned, as an etiologic factor in the discontinuance of breast-feeding, the interference of relatives. This is often carried to extremes, especially by those who have had little if any experience, as when a maiden aunt who never gave birth to a child advises against nursing. Trained nurses are often responsible for unasked-for advice which leads to a discontinuance of the breast-food. I should not tolerate any interference from the nurse in a matter of this kind. Feeding and the care of the breast is in the hands of the physician, and the nurse should know it from the beginning. I criticize both the pediatrist and the general practitioner. So many of these cases occur among the poor and ignorant. Their physicians actually profess to know nothing about breast-feeding and still less about bottle-feeding, and yet the first thing they do when they meet colic and green stools is to put the baby on some patent food. I think that this criticism of the general practitioner is just. I think that the reason he is at fault, and this is where the pediatrist deserves censure, is that the pediatrist sets him a bad example by being a little too much in a hurry to put the child on the bottle. I will not put a baby on the bottle without a good sound reason.

Dr. Chapin's proposition is a fair one. I usually get at the women psychologically as best I can. I start out with the proposition that they can nurse and explain to them the advantages which will accrue to their infant, themselves and their husbands. Then I convince them of the importance of weighing the child before and after nursing to demonstrate to them that they have enough milk. Weekly weighings are insisted on, not oftener, to show them that their babies are gaining. Sometimes I will admit that I cheat a little bit in the beginning and tell the mother the infant has gained even if it has not. I think it is best to do this in order to encourage her. Soon the gain is inaugurated in nearly every case. Then I study the milk. If I find any ingredient at fault I increase or diminish it by regulating diet, fluids, laxatives and exercise. I always flood them with water in the beginning whether the milk is good or bad. This increases the total quantity and aids the infant's digestion. The quality can be controlled later. I wish again to emphasize the importance of the psychic element. There is only one type of woman that occasionally appears to be practically hopeless, and that is the very fat woman who has more fat than glandular substance.

# A THEORY OF THE CAUSE OF ECTOPIC PREGNANCY

OTTO V. HUFFMAN, M.D.
ALBANY, N. Y.

Various speculations have seemed to explain the cause of ectopic pregnancy because, as we shall see later, they contain an element of truth so far as based on secondary causes present in only a few cases. Webster[1] was the first to formulate a working hypothesis comprehensive enough to embrace most of the observed phenomena and sufficiently fundamental to be a means to furthering our knowledge of the cause, when he definitely stated that the ovum always embeds in Müllerian tissue. At the time he formulated this hypothesis he had in mind that ectopic pregnancy always originates as tubal pregnancy; that is, the ovum embeds in the tube and not in the ovary (ovarian pregnancy) or in the peritoneum (abdominal pregnancy); but later, after undoubted cases of ovarian pregnancy were observed, he explained them as due to the extension of Müllerian tissue into the ovary. This hypothesis of Webster's leaves still unexplained the cases of abdominal pregnancy believed by some authorities to occur; it also is too speculative by attempting to explain embedding at an abnormal site as caused by reversion of the tissue-cells through degeneracy.

In stating that the ovum always embeds, in cases of extra-uterine pregnancy, in anomalous embedding areas; that is, in specialized tissues which, when normally situated, are in the endometrium, I formulated a theory that explains the cause of ectopic pregnancy wherever it might be located.[2] Before proving this theory by submitting further evidence I shall review briefly our knowledge of the early stages of human pregnancy and look into the causes of ectopic pregnancy as stated by others.

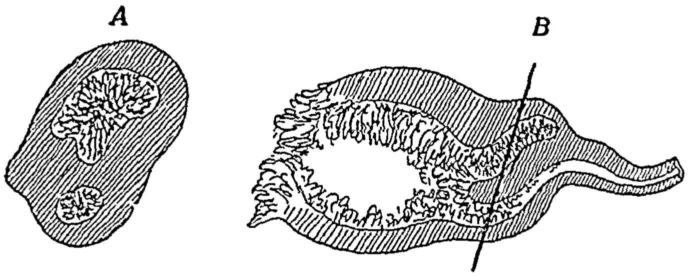

Fig. 1.—Outline sketch of sections from a tube which contained a six weeks' ovum; the ovum was situated proximal to the diverticulum; A, transverse section taken from plane indicated at B.

### KNOWLEDGE OF THE EARLY STAGES OF HUMAN PREGNANCY

No one has observed a human fertilized ovum before it has become embedded, and hence nothing is definitely known in regard to the ovum from the time of its discharge from the ovary up to the time of its nidation in the endometrium. The earliest embedded ovum found in the uterus is the one described by Hubert Peters.[3] The external dimensions were 2.4 by 1.8 mm. and the internal dimensions 1.6 by 0.8 by 0.9. The embryo was 0.16 mm. in length. The uterus containing the embedded ovum was removed at necropsy within a few hours after death from a woman who had committed sui-

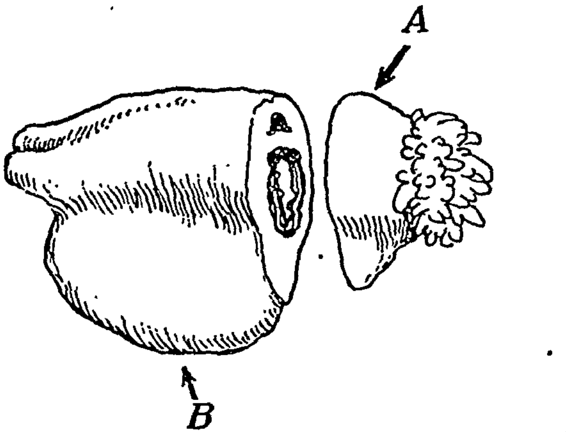

Fig. 2.—An outline sketch to show the relative size and situation of a large diverticulum which communicated with the main lumen near the fimbriated end. A small ovum was situated in the part represented at A. The diverticulum lies parallel to and below the main tube; it is much smaller at the isthmus where it again communicates with the main lumen; B indicates the ovary.

cide. The history of the case showed that thirty days had elapsed since the beginning of the last menstrual period, and that two days had elapsed since the omitted period. The age of this ovum was about fourteen days. It was apparently larger than an ovum from another case, aborted sixteen and a half days after cohabitation, and described by Bryce, Teacher and Kerr.[4] These ova, which had become securely embedded and which had been fecundated for a number of days, were not so very much larger than mature, non-fertilized ova in the ovary, the greater diameter of which is given as 0.25 mm. by Waldeyer, and as from 0.22 to 0.32 mm. by von Ebner.

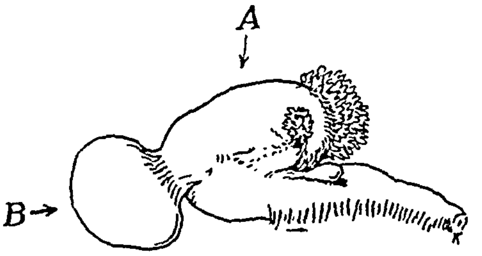

Fig. 3.—Tubal pregnancy in a malformed tube; *A*, situation of the ovum; an accessory ostium is present and below it there is a small cyst derived from the epoophoron; *B*, large cyst in the subserosa situated where the tube is curved back upon itself.

In the matter of computing the duration of gestations it should be kept in mind that we have no definite act or criterion which indicates the beginning of pregnancy. The act of insemination may be quite remote from that of fertilization because spermatozoa remain alive in the uterus and tubes for a number of days. Strassmann found human spermatozoa alive one week after coition and Bossi records a case in which they lived for more than twelve days. Dührssen[5] found living spermatozoa in a woman who stated that three and a half weeks had elapsed since having had coitus. Just when and where the spermatozoa fertilize the ova, that is, the most usual site for this meeting, no direct evidence yet shows. We know, however, that spermatozoa have been found in the fallopian tubes fifteen hours after the act of insemination, as in the case mentioned by Birch-Hirschfeld in which the woman had been fatally asphyxiated by gas during coitus. We also have the observations of Dührssen, wherein he found motile spermatozoa in a fallopian tube removed at a surgical operation. Then, too, we have the cases of ovarian pregnancy and tubal pregnancy, which indicate that the spermatozoa must find their way into the tubes.

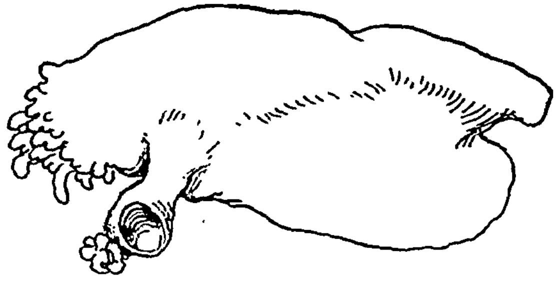

Fig. 4.—The tube from the opposite side of a case of tubal pregnancy. An accessory tube is attached to the broad ligament.

Granting, then, that the spermatozoa normally find their way into the tubes of women within a few hours after coitus, just as they do in the case of all other mammals, the next question to present itself is as to the manner in which the fecundated ovum is nourished prior to implanting itself in the endometrium; but here again we are without any absolute evidence. We do not know whether the tube is capable of furnishing nourishment by a secretion, nor do we know whether there is any secretion from the endometrium analogous to the uterine milk of some of the lower animals. On the other hand, we have evidence of the fertilized ovum influencing the maternal tissues as though by hormones, because the endometrium undergoes all the changes characteristic of pregnancy even though the fertilized ovum be retained in the tube.

If we should supplement the few observations which have been made in regard to human pregnancy with the great number which have been made on other mammals, we might safely conclude that fertilization usually occurs within the tube and that the fertilized ovum finds its way into the uterus within a day or two after becoming fertilized. We are discussing human pregnancy, however, and such analogies might only mislead us, because tubal or ovarian pregnancy, that is, primary ectopic pregnancy, does not occur in other mammals, although they are known to have extra-uterine pregnancy following rupture of the uterus. Bland Sutton,[6] who is the leading authority on this subject, has clearly shown that ectopic pregnancy in animals is caused by rupture of the uterus and is not due to implantation in the oviducts, except possibly in the one case in an ape observed by Waldeyer.

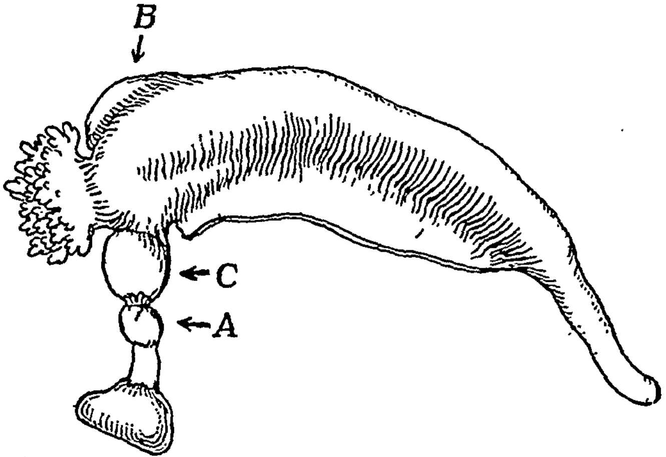

Fig. 5.—Tubal pregnancy in a malformed tube; *B*, the swelling caused by the ovum; *C*, a small cyst to which is attached an accessory tube. *A*, fringe of fimbriae which surrounds the constriction where the cyst and accessory tube are joined. Attached to the dependent end of the accessory tube there is a cyst of irregular shape.

### THE ALLEGED CAUSES OF ECTOPIC PREGNANCY

Since the majority of ectopic gestations occur in the tube, most of the theories as to the cause of this most interesting pathologic condition have been based on interference with the mechanics of the passage of the ovum from the ovary to the uterus. This interference might arise from:

1. Obstruction to the passage of the ovum.
2. Defective propelling forces.
3. An abnormal ovum.

#### *Obstruction*

Those observers who have reported ectopic pregnancy as being caused by an obstruction have found malformations of the tube, myomas or inflammatory conditions. Offsetting these findings are the results of the experiments conducted by Tainturier, Mandle and Schmidt, who ligated the oviducts of rabbits after fertilization, with the object of obstructing the passage of the fertilized ovum, but who never succeeded in producing ectopic pregnancy. One of the most interesting conditions which may affect the passage of the ovum is that described by Landau and Rheinstein,[7] and J. W. Williams.[8] These authors a number of years ago called attention to diverticula of the tube as being a possible cause, in a purely mechanical way, of ectopic pregnancy.

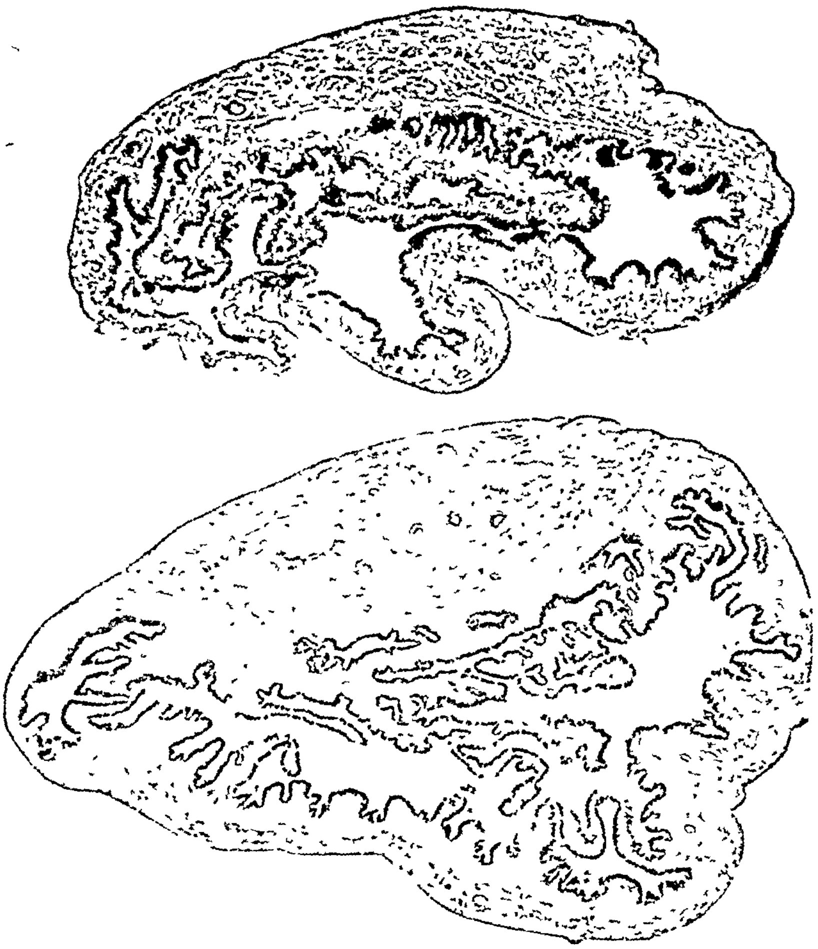

Figs. 6 and 7.—Photomicrographs (×15). Transverse sections of accessory tubes which prove their character by the typical arrangement of the mucosa in folds.

Likewise, Schatz mentioned accessory ostia as making a vortex in the currents set up by the cilia, which served to hinder the progress of the ovum in its transit through the tube. He based his vortex theory on a case of ectopic pregnancy situated in an abnormal double tube with triple communications between the two tubes, which he believed to have caused a vortex that hindered the progress of the ovum. In this connection, I wish to call attention to the fact that Werth,[9] in discussing this theory of Schatz, suggested that a tube with accessory ostia might possibly be predisposed to ectopic pregnancy. Richards, who was the first to describe accessory ostia, suggested that the ovum might drop out of such ostia and result in ectopic pregnancy. Herzog[10] studied thirty specimens of ectopic pregnancy from which he concluded that anomalies were a factor, but only as causing an obstruction. He hinted at very vital conditions, however, when he directed attention to menstruating tubes as an anomaly. Henrotin and Herzog[11] described a case of pregnancy in a blind accessory ostium. Sanger[12] likewise reported such a case.

### *Defective Propelling Forces*

Those who have reported that the propelling forces were defective believe that inflammation destroyed the epithelium. This theory was started many years ago by Lawson Tait. Subsequent observers and students such as Opitz, Micholitsch and Werth after finding inflammatory lesions in many cases of ectopic pregnancy have accepted that theory, while other students of the pathology of ectopic pregnancy, such as Kermauner and Williams, hesitate. Students of the pathology of ectopic pregnancy have never given inflammation, as a causative factor, the place that the clinicians have; for the inflammation does not necessarily interfere with ciliary motion, and inflammation in the endometrium, the normal tissue for embedding, is a most certain cause of sterility. In considering this theory of the lack of ciliary motion as being the cause of tubal pregnancy, it should be borne in mind that Lawson Tait proposed it at a time when the uterus was supposed by many to be free of cilia. In view of our present knowledge of ciliated epithelium both in the uterus and the tubes, I suggest that, if the cilia normally prevent embedding in the tubes, they should also prevent embedding in the uterus. J. W. Williams, in studying the possibility of lack of cilia being the cause of tubal pregnancy, was able to find cilia in all his specimens of tubal pregnancy, and Zedel, who also studied this question, saw the cilia in motion in several fresh specimens which he examined.

Assuming that the tube normally undergoes movements favoring the passage of the ovum into the uterus, conditions which might interfere with such movements would be hyperinvolution, either puerperal or as due to lactation; ovarian tumors, and psychic conditions affecting the tubes reflexly.

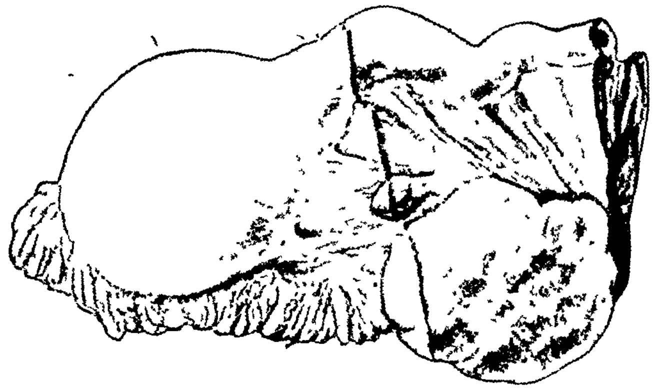

Fig. 8.—Tubal pregnancy, accessory ovary, main ovary.

### *Abnormal Ovum*

Those who have believed the ovum to be abnormal have sought evidence in an inflammatory condition of the ovary which, according to their theory, would result in the discharge of ova without the power of motility that they assume the ova to possess. Of course, this is mere conjecture on their part.

r, M.: Conception durch ein accessorisches Tubenostium; durch frühe ectopische Schwangerschaft, t, 93, i, 21.

In regard to abnormal ova, however, it is interesting to note that Robert Barnes, who was one of the earliest students of ectopic pregnancy, observed the great frequency of twins in tubal pregnancy, and that Parry confirmed his observation. In fact, the latter found that twins occur four times more frequently in tubal pregnancy than in normal pregnancy, an explanation being that a large twin ovum or abnormal ovum unable to pass through the tube embeds in it. In two cases of ectopic pregnancy which have come under my own observation there is a history of a previous twin birth. This idea is similar to the theory advanced by Sippel that the ovum, in transmigrating across the abdominal cavity from one ovary to the tube on the opposite side, consumed sufficient time to permit the growth to advance to such a degree that it would be unable to pass through the oviduct. In considering the abnormal ovum theory it should be observed that Mall has shown that 7 per cent. of all uterine pregnancies terminate in pathologic ova, that 50 per cent. of the aborted ova are abnormal, that 96 per cent. of the few unruptured tubal pregnancies which he has studied proved to be pathologic, that forty-seven out of eighty-seven tubal-pregnancy fetuses were deformed and that twelve of these eighty-seven fetuses were monstrous and only eight *certainly normal*. Although this evidence is very striking, the theory does not explain cases of ectopic gestation which have endured to term and have produced normal infants removed by operation.

There is one conjecture hinted at by the embryologists, which may be mentioned here; that is, the possibility of toxic embryotrophy being supplied by the tube. This presupposes that the ovum under normal conditions is nourished by a secretion of the tube. A poison secreted by the tube might have the same influence as physicochemical means have, when used by experimenters to produce monsters from the eggs of marine animals. Drugs or unknown conditions affecting the secretion of the tube might possibly be the remote cause.

Werth, Couvelaire,[13] Williams and nearly all observers have been able to find in tubal pregnancy a confirmation of Hubert Peters' findings in the case of normal pregnancy, but not all authorities agree as to the occurrence of a definite decidual membrane in a pregnant tube. Small areas of decidual cells may be seen, but a definite decidual membrane has never been found. Such areas of decidual cells have been observed by Williams, Webster and Couvelaire. An important observation is that of the occurrence of decidual cells in the tube opposite to the one in which the gestation has occurred. Such observations have been made by Webster, Mandle, Goebel, Janot, Krömer and Williams. Embryologists and present-day students of the decidua believe the decidual cell to be protective to the maternal organism against the too aggressive invasion by the trophoblast of the ovum. Hubrecht in his studies of the hedgehog, Webster and Bryce, Teacher and Kerr in man have emphasized their belief in the protective nature of decidual cells.

This phase of the study of tubal pregnancy has been greatly hindered by the fact that 78 per cent. of tubal pregnancies terminate in tubal abortion; and here the same phenomenon occurs as when abortion takes place in the uterus, namely, hemorrhage. This hemorrhage is so extensive that it destroys the ovum to such an extent that many specimens are rendered worthless for study. This fact, taken together with the fact that the other 22 per cent. terminate in rupture of the tube, points out very clearly the difficulties of studying this question of the occurrence of true decidua. The very early cases never reach us, because the embryo is extruded into the abdominal cavity and is absorbed—the disturbances not being severe enough to cause surgical intervention. In later cases, when an ovum undergoes death or is extruded from the tube and is too large to readily undergo absorption, suppuration may ensue. Such cases may account for some of the ectopic pregnancies which have occurred in pyosalpingitis as described by Hirst. Then, too, extra-uterine gestations have been found to be subject to all the diseases that may occur in intra-uterine pregnancy, that is, *hematoma mole, hydatidiform mole and hydramnios*, or to be associated with chorio-epithelioma and eclampsia.

### *Webster's Theory*

In 1895 J. Clarence Webster reviewed all the important literature on ectopic pregnancy and pointed out that the various explanations up to the time of his writing had been conjectures only. He, on the other hand, was able to formulate a theory which was a beginning in the right direction. Webster came to the conclusion that the ovum always embeds in Müllerian tissue. He demonstrated decidual reaction in nearly all of his cases and advanced the view that the ovum could develop only in tissue capable of undergoing such a genetic reaction. His theory, which served as a working hypothesis for all subsequent investigators, brought out the fact that the ovum does not embed in the peritoneum as once supposed. When a number of cases of ovarian pregnancy had been undoubtedly proved, namely, those described by Van Tussenbroek,[14] Thompson and others, it was thought that Webster's theory would become valueless. He soon showed, however, that Müllerian tissue might extend into the ovary. His observations were confirmed by those of de Sinety, Melassez and J. W. Williams, all of whom

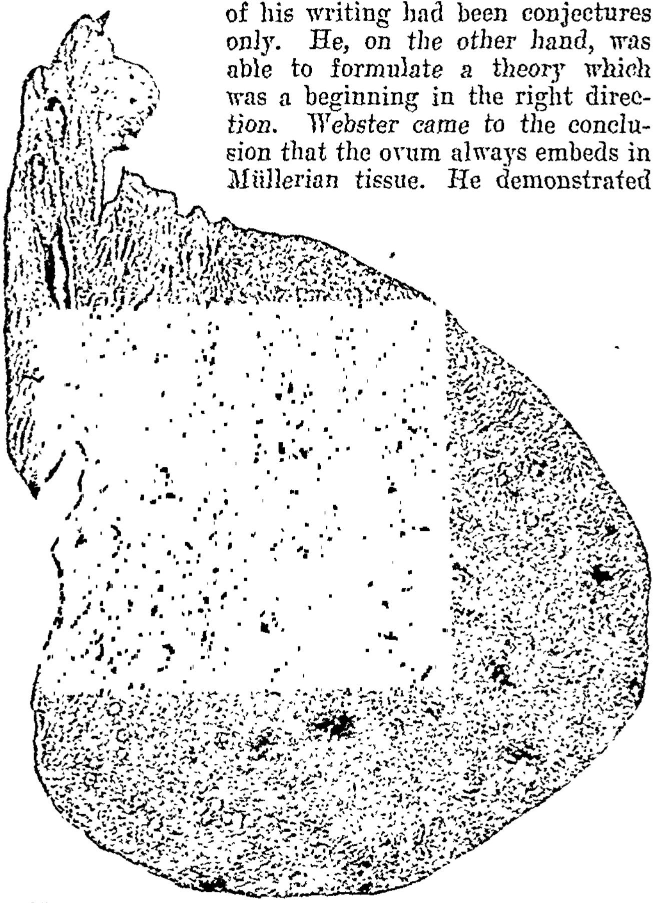

Fig. 9.—Photomicrograph (×20). Section from accessory ovary represented in Figure 8.

[13] Couvelaire, A.: Etudes anatomiques sur les grossesses tubaires, Paris 1901.

[14] Van Tussenbroek, C.: Un cas de grossesse ovarienne, Ann. de Gynec., 1899, iii, 537.

demonstrated the extension of Müllerian tissue into the ovary. Webster in his theory as to the cause of ectopic pregnancy laid emphasis on the fact that it always embeds in Müllerian tissue capable of undergoing the genetic reaction, and he later mentioned that it was doubtless the special genetic action in areas of decidua-like cells such as found by Schmorl in the ovary in normal pregnancy which might determine embedding in the case of ovarian pregnancy. Small areas of cells similar to decidua cells have been observed under the peritoneum in normal pregnancy and they have been termed decidual nodes. Webster's theory is, then, that implantation occurs at an abnormal site because certain cells there, originally derived from the Müllerian duct, have, through degeneracy, reverted and again acquired their decidual-reacting or genetic property.

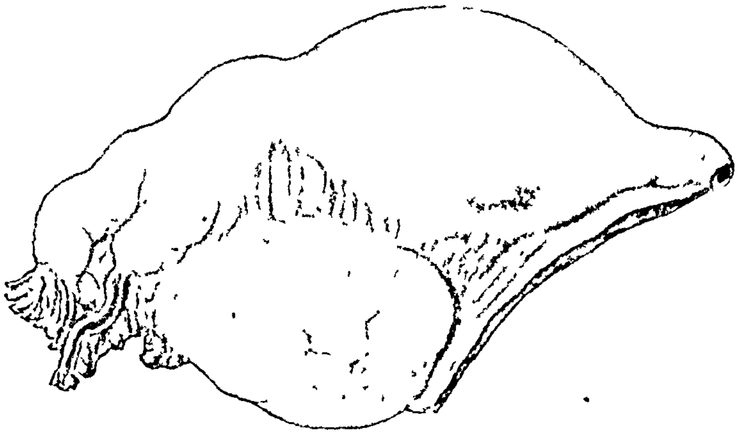

Fig. 10.—Tubal pregnancy in a malformed tube. An elongated accessory tube is attached to the main tube.

### THE ANOMALOUS-EMBEDDING-AREA THEORY

I observed and described a very remarkable specimen of ectopic pregnancy removed at necropsy. I was able to examine and study the entire uterus as well as both tubes and ovaries with a view to finding some confirmation of the inflammation or obstruction theories. My results were negative. I found, though, two supernumerary but rudimentary fallopian tubes, one attached to each of the fully developed, apparently normal tubes; which enabled me to offer an explanation for the tubal pregnancy. Starting with the fact that each tube was congenitally malformed, as indicated by the supernumerary tube, I inferred that early in the embryologic development of the individual there was a duplication of the Müllerian ducts, and that with the subsidence in the growth of one pair, those portions which should have formed a second uterus, with all the factors that determine an implantation area, became fused as "rests" with the walls of the tubes which went on to full development, and that such a rest permitted the ovum to embed. Keeping this explanation in mind, I took as a working hypothesis that ectopic pregnancy is determined by an anomalous embedding area. I called attention to the mutual physiologic relation of fecundated ovum to embedding area and referred to the localization of placentation or embedding areas in the uteri of some of the lower animals, as, *for instance*, the cotyledonary burrs in the virgin cow and the *coussinets* of Hollard in the virgin rabbit. Not being able to recognize in the morphologic details of such areas anything that characterized the special tissue or factor essential to embedding, I could not support my hypothesis by direct evidence, so I set about to examine a large number of specimens of ectopic pregnancy with a view to finding some gross anomaly or malformation which would point to the probable misplacement of embedding tissue during the maldevelopment. Out of twenty-four specimens of tubal pregnancy removed by operation, only nine could be examined with certainty for minor anomalies. The other fifteen specimens were too extensively damaged by the large size of the gestation, the rupture or adhesions, to determine positively whether or not an anomaly existed. Of the nine that could be examined I found one with four accessory ostia, one with an accessory ostium, two with accessory tubes attached to the broad ligament and one with accessory ovaries. Two of the specimens which did not show an anomaly were accompanied by the tubes from the opposite side that had been removed at the time of the operation for the ectopic pregnancy. One of these non-pregnant opposite tubes had an accessory ostium and the other one was short and rested on a parovarian cyst. Of the remaining three apparently normal tubes, one was associated with an ovarian cyst 5 cm. in diameter, evidently derived from the rete ovarii.

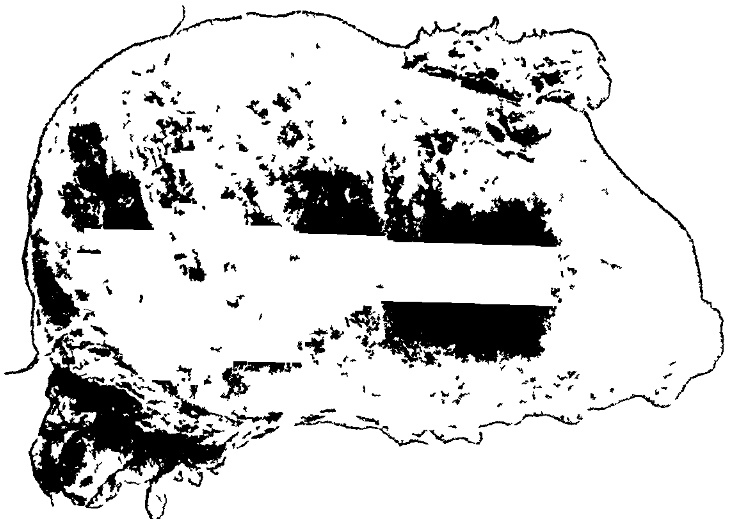

Fig. 11.—Tubal pregnancy with rupture and hemorrhage. The chorionic villi protrude from the rupture; the tube is greatly dilated by blood-clot; the fimbriae are edematous. This is a common type of specimen.

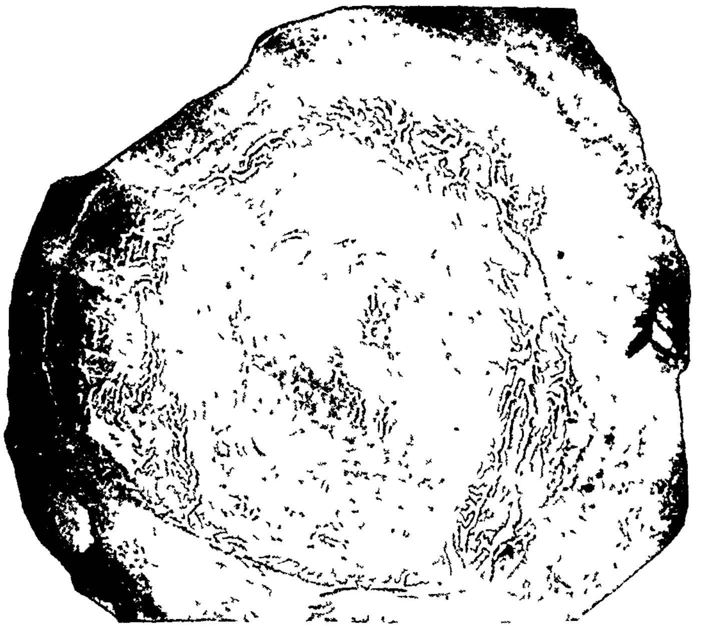

Fig. 12.—Photomicrograph (×4). Transverse section of a fallopian tube distal to the attachment of the ovum. The anomalous condition of a tube within a tube. The tube in the center has a thick muscularis which is surrounded by mucosa thrown into folds which project into the circular lumen. The outer wall of the circular (outer) lumen is composed of mucosa, and, in turn, a muscular layer. The central lumen is lined with normal mucosa. The central lumen ends blindly near the isthmus.

In addition to reporting these findings, I also applied this hypothesis to an interpretation of a very early tubal pregnancy described by Rubin.[15] In Rubin's specimen a very small ovum was found embedded in the tube, proximal to a thickened muscular spur that, in turn, was proximal to a diverticulum of the tube. Rubin regards the spur as having arrested the ovum before it even reaches the diverticulum. His explanation seems too simple; with my hypothesis in mind the spur and diverticulum should be regarded as evidence of maldevelopment. Likewise in a case of ovarian pregnancy described by Graham,[16] in which a remnant of fallopian tube was found in the ovarian mass, I probably should regard it as a malformation or ingrowth of Müllerian tissue into the ovary, while Graham believes it to have been twisted off and separated from the tube by the growth of the ovum.

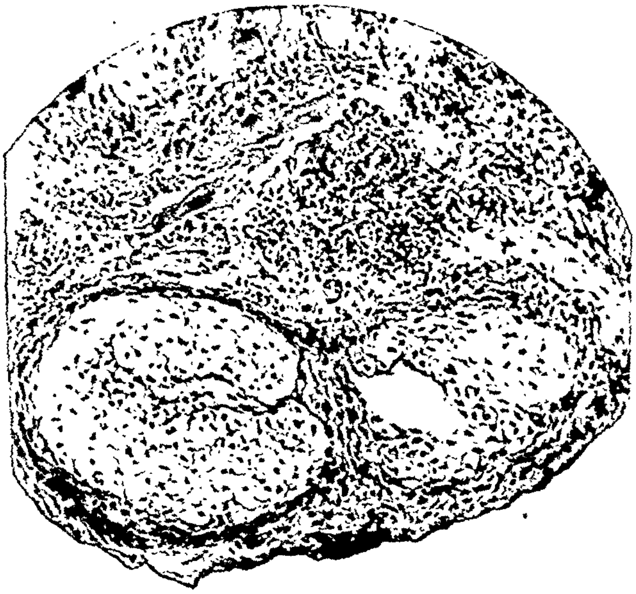

Fig. 13.—Photomicrograph (×250). Nest of decidua-like cells found in the wall of a tube near the peritoneum. The cells seem to be arranged around an endothelial lining which they have crowded in and they seem to have partially obliterated a lumen or space.

### *Further Evidence*

It is in support of my theory that I wish to report further evidence. Before doing so I shall review in logical sequence certain findings which permit approach by steps, as it were, to the theory of an anomalous embedding area.

1. Mauriceau and others have described cases of pregnancy in a rudimentary horn of the uterus.
2. Kehrer has collected eighty-four cases of cornual pregnancy from the literature, in 78 per cent. of which there was no communication between the rudimentary horn and the fully developed horn, the pregnancy having been the result of the transmigration of either the spermatozoa or the fertilized ovum to the rudimentary horn.
3. Henrotin and Herzog, and Sänger have described cases of ectopic pregnancy situated in blind accessory fallopian tubes.
4. Cases of ectopic pregnancy associated with accessory tubes and ovaries have been described by me.

I have examined sixty-eight specimens of tubal pregnancy. In each one I looked for an obstruction, signs of inflammation, and evidences of maldevelopment. In none could I find an obstruction. Some showed mild grades of inflammation which were readily accounted for by the invasion of alien cells and the hemorrhage. I found malformations in thirty-seven specimens:

Six had large irregular diverticula which could not have been caused by the growth of the ovum (Figs. 1 and 2).

Five had accessory ostia (Fig. 3).

Three were associated with anomalies of the opposite tube (Fig. 4).

Two presented such an anomaly as represented in Figure 5.

Two had accessory ovaries (Figs. 8 and 9).

One had an anomalous tubule attached to the broad ligament.

Five had accessory tubes (Fig. 10 and Figs. 6 and 7).

Nine were simple dilatations of the tube by the growth of the ovum (Fig. 11).

One showed a most unusual anomaly, a tube within a tube (Fig. 12).

Three showed nests of decidua-like cells (Fig. 13).

All of the anomalies found were examined microscopically in order to prove definitely their exact nature.

In none of the specimens was I able to find a true decidual membrane. When the ovum was still *in situ* it was found embedded beneath the mucosa which, with the blood-clot, covered it on the side next to the lumen of the tube, while on the side next to the muscularis it was attached to a rich layer of cells derived from the trophoderm which had invaded the maternal tissues. These cells and the secondary inflammation caused by them gave an appearance, in some cases, that might readily have been mistaken for tuberculous inflammation, which in former years was given quite a place as a cause of ectopic pregnancy. In recent years less has been written about tuberculous inflammation as a cause of ectopic pregnancy, and I take this to be due to our better knowledge of the cells derived from the trophoblast, of the syncytial cells and of foreign-body giant-cells.

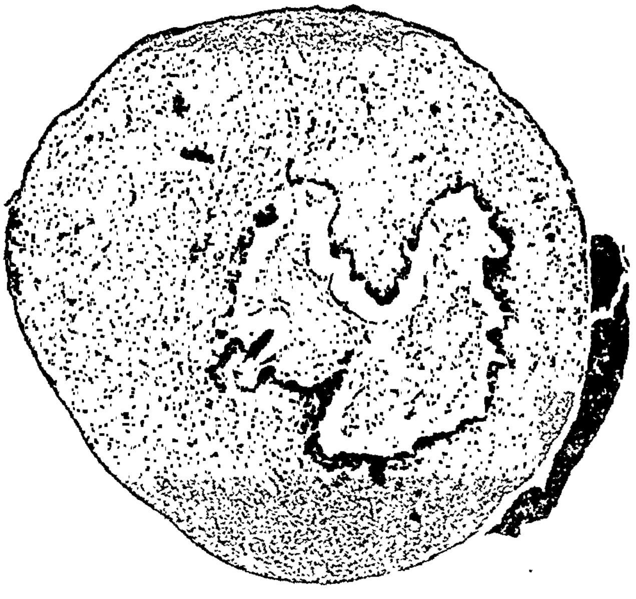

Fig. 14.—Cross-section of an accessory tube attached to the broad ligament of a tube which had a nest of decidua-like cells near its peritoneal surface.

We also have more knowledge of the membrana decidua compacta, which we now know not to occur as a regular distinct membrane in a pregnant tube. I could find no true decidua in any of my tubes. In three there

# ACCIDENTS IN TRANSFUSION

## THEIR PREVENTION BY PRELIMINARY BLOOD EXAMINATION: BASED ON AN EXPERIENCE OF ONE HUNDRED TWENTY-EIGHT TRANSFUSIONS *

REUBEN OTTENBERG, M.D.
AND
DAVID J. KALISKI, M.D.
NEW YORK

Accidents following transfusion have been sufficiently frequent to make many medical men hesitate to advise transfusion, except in desperate cases. It has been our opinion since we began making observations on this question in 1908 that such accidents could be prevented by careful preliminary tests, leading to the exclusion of agglutinative or hemolytic donors. Our observations on over 125 cases have confirmed this view and we believe that untoward symptoms can be prevented with absolute certainty.

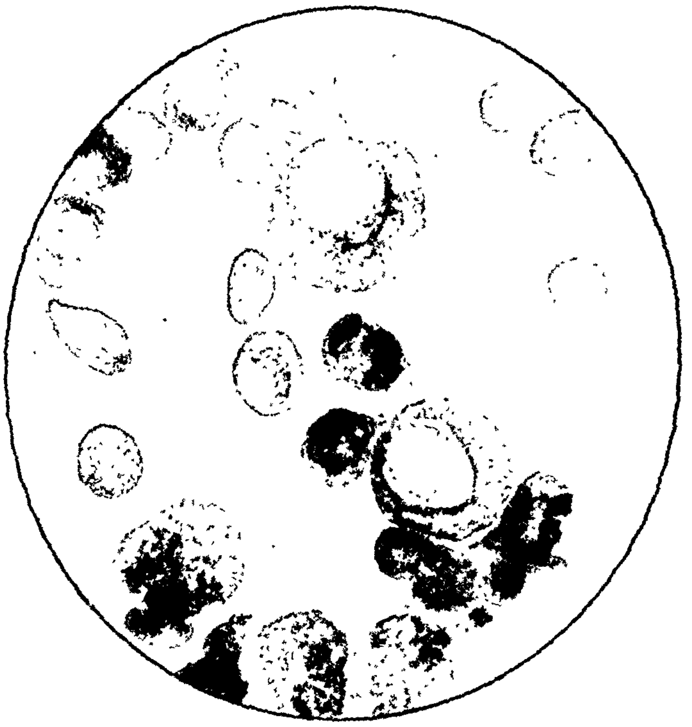
It has been the general impression that preliminary blood-tests ought to be done to determine the compatability of the donor's with the patient's blood, but there has been little direct observation as to the correspondence between the test-tube phenomena of agglutination and hemolysis and symptoms arising after transfusion.

Scattered reference to the hemoglobinuria following transfusion have made it clear that the occurrence of hemolysis between the donor's and patient's blood is a real danger. Thus, Flörcken[1] reports hemoglobinuria in two out of five cases which he transfused, and Gray[2] reports hemoglobinuria in one out of three transfused cases. Suttner,[3] reporting four transfusions, says: "One case resulted fatally from hemolysis, which might have been prevented had not its urgency required prompt action." Pool[4] reports a case of delirium and extreme jaundice following transfusion. In the case of Pepper and Nisbet,[5] a fatal hemoglobinuria followed a second transfusion for pernicious anemia. Cases have been reported by Crile,[6] Watts[7] and others. Rehling and Weil[8] report a case with severe hemoglobinuria which was anticipated by blood-tests. Undoubtedly many other cases that have occurred have never been reported.[9]

The question whether or not interagglutination is a danger in transfusion is still an open one. Our experience leads us to believe that its occurrence under certain circumstances may vitiate the result of transfusion and should be avoided, although no one has yet shown that it causes extensive thrombosis or embolism as we feared at first. The few observations of Schultz do not bear directly on the question because his transfusions were small in amount as compared with the amount usually transfused by the direct method.

In emergencies and occasionally at other times, relatives or friends of the patient have been used as donors. Their blood should of course be tested. Iso-agglutinins are inherited, as first pointed out by Ottenberg[10] in an article with Epstein, published in 1908. No certainty can be secured, however, without examination, as each individual inherits from either one of his parents.

We shall omit any detailed reference to the technic of agglutination and hemolysis tests. We use a modified Wright's capillary pipet method, first described by Epstein and Ottenberg.[11] This method has the advantage that it requires only as much blood as can be obtained from a finger prick from both patient and donor. With this method it is possible to examine ten or twelve donors within two or three hours.



Blood-smear of patient made during transfusion. The patient's serum was agglutinative to the donor's blood-cells. Phagocytosis was observed only in cases of this kind.

We have always performed Wassermann tests on prospective donors. The necessity of this has been demonstrated by the finding of five positive Wassermann reactions in prospective donors. In a well-equipped laboratory the Wassermann and other tests can be performed simultaneously and all can be completed within three hours.

### HEMOLYSIS

The hemolysis of one human blood by another is a pathologic phenomenon. It was formerly thought to be characteristic especially of carcinoma and tuberculosis, but it has been shown[12] to occur in a great variety of diseases.

---

[11] Epstein, A. A., and Ottenberg, R.: A Method for Hemolysis and Agglutination Tests, Arch. Int. Med., May, 1909, p. 286.

That it is necessary to make tests of this kind if hemolytic accidents are to be avoided, is evident from the fact that the blood of seventeen out of 128 of our patients was actively hemolytic for several different donors, as well as from the published reports of accidents and fatalities in cases in which preliminary tests had not been made.

The diseases in which hemolysis was observed were:

| | Cases |
|---|---|
| Purpura hemorrhagica | 2 |
| Carcinoma of the stomach | 3 |
| Carcinoma of the rectum | 1 |
| Lymphatic leukemia | 4 |
| Pernicious anemia | 2 |
| Chronic osteomyelitis (due to *Staphylococcus aureus*) | 2 |
| Pelvic abscess | 1 |

There were three instances of reverse hemolysis, that is, hemolysis of patients' cells by donors' serum. The first was in a patient who was suffering from postoperative hemorrhage. On subsequent examination the donor was found to be suffering from tuberculosis. The others were in a case of pelvic abscess and a case of pernicious anemia.

In all except two of the cases cited the patients' serums were hemolytic with only some, but not all, of the prospective donors' bloods, and by examining a certain number of men, one was eventually found who was not hemolytic with the patient. In two of these instances, on account of the desperate condition of the patients, hemolytic transfusions had to be ventured. In two additional cases (not included in the list) transfusion had to be abandoned because the serum of the patients was powerfully hemolytic to the cells of every donor examined. One of these was a case of lymphatic leukemia, and the other of pernicious anemia.

One of the hemolytic transfusions was done in a case of pernicious anemia. The serum of this patient was agglutinative and weakly hemolytic to the cells of the donor. The transfusion was followed by an intense hematuria which lasted about twenty-four hours, during which the hemoglobin dropped from 34 to 31 per cent., instead of rising further, as almost invariably happened after transfusion in other cases. In spite of the loss of the transfused blood, transfusion apparently exerted a favorable influence on the course of the disease, as the patient improved slowly but steadily during the following month.[13] The patient returned to the hospital eight months later, and a second transfusion was done. This time a donor was found whose blood did not agglutinate or hemolyze when mixed with that of the patient, although the patient's serum was hemolytic to the cells of four of ten donors. This transfusion was successful; the patient was greatly improved, and her life was prolonged for a year and a half.

In the other case (one of acute lymphatic leukemia), in which test-tube hemolysis was noted between the blood of the patient and that of the donor, the patient's serum sharply agglutinated the donor's cells, but only slightly laked them after three and one-half hours in the thermostat. There was no hemoglobinuria, but blood-smears made during and after the transfusion showed phagocytosis of red blood-cells by leukocytes in the circulating blood. The patient died forty-two hours after the transfusion. The case will be more fully discussed later under the heading of agglutinative transfusion (see photomicrograph).

In only four other cases in the whole series were any red blood-cells found in the urine after transfusion, and in these four cases they were found only in small numbers in the centrifuged sediment.

Jaundice occurred after transfusion in only one case in the series, and in this it was slight and transient, disappearing in two days. It may have been due to some other cause, as the patient had a carcinoma of the stomach (Old Series, No. 46).

The absence of hemoglobinuria in over one hundred cases in which hemolytic donors were excluded by examination and its occurrence only once in the whole series, and then in a case in which the test-tube hemolysis had been noted, proves that the danger of hemolysis can be absolutely excluded by careful preliminary tests.

### AGGLUTINATION

Iso-agglutination, unlike isohemolysis, is not a pathologic phenomenon, but occurs between normal human bloods. All human beings fall into four permanent hereditary and sharply separated groups with regard to whether their serums agglutinate each other's red blood-cells or not. When the blood of two persons belonging to the same group is mixed, no agglutination occurs. When the blood of two persons of different groups is mixed, agglutination, either of one by the other or of each by the other, always occurs.

It is not necessary here to go into details of the grouping. The important questions are whether or not it is necessary to pay attention to agglutination in selecting donors and what the influence of agglutination is on the result of transfusion.

Human iso-agglutinins are present in only relatively weak concentration, generally not being active at all in greater dilution than 1:10 or 1:20. All the agglutinin present in a given volume of serum can be absorbed by a small volume of susceptible cells.[14] The result of this is that, when a given volume of serum is mixed with a large volume of susceptible cells, the individual cells are only feebly sensitized and no gross agglutination is seen.

In the instance in which the serum of the donor is agglutinative to the cells of the patient, the plasma of the donor on transfusion will be diluted by an excess of the patient's plasma and will meet with a large excess of the agglutinable cells. These are the conditions under which, in vitro, the minimum amount of agglutination, if any at all, is observed. In practice, in all such transfusions, as we shall show later, no unfavorable results were obtained (four instances).

When the patient's serum is agglutinative toward the donor's cells, the conditions for sensitization of the cells of the donor are much better, as a smaller bulk of blood-cells is introduced into a larger volume of agglutinative plasma. Even here, however, it is probable that only in exceptional instances can massive clumps of agglutinated cells be formed, such as are seen in the test-tube when a dilute suspension of the cells is mixed with agglutinative serum and allowed to rest quietly until agglutination is complete. There is no doubt, however, that some sensitization of the cells occurs under these conditions. It is in these cases only that phagocytosis of red cells in the circulating blood has been observed, twice by us and once by Hopkins.[15]

[12] Ottenberg, R., and Epstein, A. A.: The Diagnostic Value of Hemolysis in Cases of Cancer, Arch. Int. Med., June, 1909, p. 467.

[13] It is possible from the work of Hess and Saxl (Deutsch. Arch. f. klin. Med., 1912, cviii, 181), that the material from some of the destroyed cells may have been used in the reconstruction of blood.

[14] Ottenberg, R.: Transfusions and the Question of Intravascular Agglutination, Jour. Exper. Med., 1911, xiii, No. 4.

We have seen four transfusions in three cases in which the serum of the donor was agglutinative to the cells of the patient. There were no untoward symptoms in any of these four transfusions. In two of the four transfusions numerous blood examinations showed absence of phagocytosis in the circulating blood. In the other two transfusions no search was made for this. Of these three patients, one, with gastric ulcer, ultimately recovered completely while the other two died within a few days of causes that had nothing to do with the transfusion (shock, following resection of the stomach in one instance, and liver abscess in the other).

We have seen three transfusions in which the serum of the patient was agglutinative to the cells of the donor. In two of these instances, already cited, the serum was also slightly hemolytic.

In the first of these (referred to previously), an intense hematuria occurred. This was one of the early cases and no observations were made as to the occurrence of phagocytosis. In the second case, one of acute lymphatic leukemia, the patient's serum was agglutinative and slightly hemolytic to the donor's blood-cells in three and one-half hours. Blood smears at the completion of the transfusion showed phagocytosis of the red blood-cells by polynuclear leukocytes. The patient died forty-two hours after the transfusion. There was no hematuria in this case, but the amount of hemolysis in the test-tube was minimal.

The third instance in which the patient's serum was agglutinative to the donor's cells was also a case of pernicious anemia. Blood-smears made five minutes and fifteen minutes after the start of the transfusion and at the end of the transfusion showed phagocytosis of red blood-cells by polynuclear leukocytes (see photomicrograph). The patient passed no urine after the transfusion, and died eight hours later. Necropsy revealed an extensive phagocytosis of the red blood-cells in the microscopic sections of the lymph-nodes and spleen.

The occurrence of phagocytosis of the red cells in the circulating blood is an exceedingly rare phenomenon and is in every instance due to injury or destruction of red cells. Aside from the present instances, it has been described as occurring, so far as we have been able to find, only in paroxysmal hemoglobinuria and in potassium chlorate poisoning.[16] Our control observations of over thirty non-agglutinative and non-hemolytic transfusions show that the phagocytosis was not due to the nature of the diseases (pernicious anemia, leukemia) in which it occurred, because among the control cases were several cases of each of these diseases with no phagocytosis after transfusion.

In the great majority of cases transfused in which hemolysis and agglutination have been excluded by tests, febrile reactions following transfusions have been entirely absent. In a considerable number of cases (twenty-one out of 128), there have been slight febrile reactions, lasting one or two days, probably to be regarded as ordinary surgical fever. In less than 10 per cent. of the cases (ten cases in 128), more severe reactions occurred, often with chills, occasionally with vomiting. In none of these cases did symptoms last more than two days. In none of them did hemoglobinuria or hematuria ensue. The occurrence of these symptoms has been variously attributed by some authors to hemolysis or agglutination, or (by German authors who studied indirect transfusion) to the transfusion of fibrin ferment.

The first two causes can be excluded in our cases. Fibrin ferment cannot be a factor because the transfusions were direct artery-to-vein or vein-to-vein transfusions; nor do the pathologic conditions for which the transfusions were done in the cases that had severe reactions throw any light on the cause of their occurrence.

The same thing is true of skin eruptions which occurred in about 10 per cent. of the cases. The cause of skin eruptions is evidently connected with the cause of severe febrile reaction, because five of the eleven cases which showed skin eruptions were in the group which showed severe febrile reactions. Two of the instances of skin eruption were cases of severe general erythema, and it is interesting that in both of these cases the blood-serum of the patients was powerfully hemolytic for the blood-cells of the majority of proposed donors, but the particular donor chosen was one whose blood-cells were not laked. It seems, therefore, as though the cause of the extensive skin eruption in these cases had some connection with the cause of the hemolytic poison, but was not identical with it.

## SUMMARY

1. Accidents in transfusion due to the occurrence of hemolysis or agglutination of the donor's blood-cells by the patient's serum, or vice versa, can be absolutely excluded by careful preliminary blood-tests. We have been able to prevent accidents of this kind in 125 transfusions.

2. The relation between test-tube hemolysis and intravascular hemolysis is close, and it seems likely that in all cases in which there is test-tube hemolysis, some intravascular hemolysis occurs. When this exceeds a certain limit hemoglobinuria results.

3. The occurrence of agglutination (between the blood of the donor and that of the patient) need not be regarded as an absolute contra-indication to the transfusion, but non-agglutinative donors should be chosen whenever possible.

4. Phagocytosis of red blood-cells by leukocytes in the circulating blood of the patient transfused is undoubtedly connected with interagglutination of the two bloods; it occurred in our series in two cases in which the serum of the patients was agglutinative toward the cells of the donors (in one of the cases the serum was also hemolytic), and it did not occur in any of thirty-five non-agglutinative transfusions in which it was carefully looked for. These negative cases included two cases with extensive urticaria and one case with severe febrile reaction after transfusion. In the cases in which the serum of the donor was agglutinative toward the cells of the patient, no phagocytosis of red cells in the circulation was seen.

5. In selecting donors with regard to agglutination, the agglutination of the donor's cells by the patient's serum is more important to avoid than the reverse.

6. Febrile reactions or urticaria and other skin eruptions occur after about 10 per cent. of transfusions, irrespective of hemolysis or agglutination, and are not due to fibrin ferment or to blood platelet destruction. These reactions, however, are never serious and the patients have done well in spite of them.

The authors wish to thank Dr. F. S. Mandlebaum for the photomicrograph.

# A STRIKING ACQUIREMENT OF VISUALIZING POWER AND THE DEVELOPMENT OF DREAMS FOLLOWING A CEREBRAL TUMOR EXTIRPATION

ERNEST G. GREY, M.D.
AND
L. E. EMERSON, Ph.D.
Psychologist, Massachusetts General Hospital; Examiner in Psychotherapy, Psychopathic Hospital
BOSTON

The relation of intracranial growths to mental activity is recognized as a very intimate one. Most of us are familiar with the changes in memory and disposition, the states of hebetude, lethargy and stupor, the decrease in power of attention, the so-called "dreamy states," the abnormal emotional states, fatigueability, etc., associated with cerebral tumors and their usual concomitant state of increased intracranial tension. Pfeifer[1] has recently given quite a complete summary of the mental disturbances found in these types of cerebral cases.

The relation of brain tumors to mental imagery, however, seems to have called forth but little comment.

Since 1880, when Galton made his classical study of the visualizing faculty, students of psychology have been able to classify persons in this respect. We have known that memory, that is, knowing and remembering, takes place by means of visual images, by auditory images, by motor and tactile images or by various combinations of these types—the usual method. The case we have to present represents a striking example of the appearance (reappearance probably) of the visualizing power following immediately—a matter of hours—in the wake of a cerebral tumor extirpation.

## HISTORY OF CASE

*Patient.*—Miss H., aged 22, teacher of domestic science, born in Massachusetts, of American parentage. Service of Professor Cushing in the Peter Bent Brigham Hospital, Boston. Patient comes from a cultured family; her father is a professional man. There is nothing similar to patient's trouble on paternal or maternal sides. Personal history unimportant except that twelve years ago patient was struck with a croquet mallet over the right parietal region (area of tenderness found in examination), causing a severe nosebleed. Patient does not recollect having been unconscious or confined to bed. She has always been stout since puberty. She was a student until June, 1912, when she was graduated from a college in Boston. Though the school work had been constantly heavy, she enjoyed it and was able to complete her studies more or less successfully. (See later notes.)

*Present Illness.*—Vision: Blurring of vision began in January, 1912. The retinal vessels were found to be tortuous. Her glasses were changed and symptoms disappeared until December, 1912. At this time patient complained of eye-strain. In January, 1913, she began to have difficulty in accommodation, followed by decrease in visual acuity. On admission to the hospital patient had "spells" in which it was difficult for her to differentiate people.

Paresthesia: Numb-tingling sensations began in April, 1912. First noticed in left upper extremity, beginning in hand and extending to pectoral region and left side of face. Tongue and buccal mucous membrane involved. Came in brief attacks; later immediately antedated.

Convulsive Seizures: The first definite convulsion appeared at night, August, 1912; it involved the entire body. In the beginning such attacks were repeated at intervals of a month. Later they became more frequent and more severe. A typical attack consisted of: sensory aura (previously referred to) without cry; there was an indefinite feeling of malaise and severe headache with twitching of fingers of left hand, followed by involvement of hand, forearm and upper arm, in order; loss of consciousness and convulsion of entire body; cyanosis; frothing at the mouth; labored breathing and involuntary micturition. Duration, a few minutes. Consciousness recovered in about fifteen minutes; tired and "used-up" feeling, but fairly bright.

Headache: This was severe in and following seizures. Between attacks slight occipital and posterior cervical pain, "neuralgic" in character. Some headache as a junior in college.

Vomiting: This occurred at the onset of a few attacks and was not often projectile in character; occasionally not associated with seizures. There was some nausea.

Pain in Left Pectoral Region and in Left Arm: First noticed in June, 1912, together with the numb sensations. Later the patient experienced also a severe, throbbing, burning sensation in these parts.

Dizziness: This was occasionally present when arising in the morning. Sometimes, in descending stairs, this necessitated holding on to the banister, but patient never fell. Objects at no time appeared to move.

*Physical Examination.*—Thorax and abdomen unimportant. Blood-pressure 110 (Tycos). Blood: White blood-cells, 8,900; hemoglobin, 100 per cent. (Sahli). Urine not unusual. Temperature and pulse normal.

*Neurologic Study.*—(Drs. Cushing and Bagley)—Head: Marked tenderness over right posterior parietal region.

Skin: Firm and elastic. Rather marked panniculus, evenly distributed.

Cranial Nerves: Unimportant except for,

N. II: Eye-Grounds (Dr. Clifford Walker). Fundus right eye, acuity 20/30. Disk elevated 7 D. Entirely obliterated by new tissue formation of considerable duration, under which engorged and tortuous veins and narrow arteries were deeply imbedded. A few punctate hemorrhages with one large flame-shaped hemorrhage. Peripheral fundus slightly edematous. Fundus left eye, acuity 20/40. Disk elevated 7½ D. Otherwise much as in right eye.

N. III: Right pupil larger than left. Both sluggish to light, right more than left.

Cerebrum: Frontal.—Slight disturbance in memory (of recent appearance) for names and small events. Temporal.—No aphasia; no uncinate gyrus symptoms; no hemianopsia (no constriction of form fields. Slight constriction for colors in left eye. No scotomas made out). Parietal.—(sensory) Paresthesia with attacks. Touch, pain and temperature good. Muscle sense good. No astereognosis. (Motor) Epileptic attacks. Marked muscle fatigue following slight exertion, especially in left arm. Occipital.—No hemianopsia. No visual hallucinations.

Cerebellum: Romberg negative; no nystagmus. No disturbance of gait. Some dizziness. Diadokokinesia much better with right arm. No definite ataxia, though left arm moved less well than right.

Reflexes: Superficial.—Elicited. Deep.—Knee- and ankle-jerks not obtained on either side.

Sphincters: Loss of bladder control in attacks.

Vasomotor: No changes.

Extremities: Uses left and right hands equally well.

*Operation.*—On March 28 Dr. Harvey Cushing performed a right exploratory craniotomy and decompression. A generous-sized bone-flap was turned down from the parietal region. There was a depressed area in the dura just below the parietal eminence, corresponding to the tender spot on the skull found during the examination. There was also a kind of conical protrusion of the inner table of the skull about the size of a five-cent piece extending to a fairly sharp point. The dura was fairly tense and unusually vascular. By reflecting the peripheral dura upward a definitely demarcated area of dark red appearance was seen in the parietal cortex which proved to be new growth. A small isolated island of dura was left, about 5 cm. in diameter, which was attached to the underlying tumor mass. This occupied the region of the angular gyrus. The new growth was carefully dissected from the surrounding cortex and finally delivered in toto. It was quite vascular and had a soft, pulpy consistency. At no point did it seem to invade the cortical substance. The cavity left in the hemisphere gradually filled in, so that within a short time the brain had resumed its normal outlines; in fact, tended to protrude from the dural opening. The exostosis of the inner table was rongeured away and the bone-flap replaced.

---

[1] Pfeifer: Arch. f. Psychiat., xlvii, 2, 558, 1912.

*Pathologic Report.*—(Dr. Rhae). The fresh tumor measures 4.8 by 2.6 cm. by 4.6 cm. Weight, 48.5 gm. Microscopic sections made in the plane of its greatest diameter are roughly hemispherical with a slight concavity on the flattened side. Throughout the greater portion of the section there is a limiting capsule of dural tissue. The tumor itself shows a connective tissue stroma, a good blood-supply and numerous tumor-cells. The latter vary little in size. Their nuclei are oval and most of them have a distinct nucleolus. No fibrils are demonstrated in connection with them and none show mitosis.

Diagnosis: Endothelioma of the dura.

*Recovery.*—Patient came out of the ether rapidly and by 9 p. m. was in excellent condition. She conversed intelligently with those in charge of her. Discharged on the forty-sixth day following the operation with remarkable subjective and objective improvement. Convalescence uninterrupted for a number of weeks. Recently some minor epileptiform attacks.

### PSYCHOLOGIC STUDY

On the morning following the tumor extirpation one of us noted that the patient appeared to be in unusually good spirits. A little questioning revealed the fact that she was quite excited over the ability, which she seemed to have acquired quite suddenly, of making mental pictures of the objects and persons in the room, a faculty, she asserted, quite foreign to her previous capabilities. Further inquiry led to the discovery that she had dreamed during the night and that this dream consisted of mental images, which will be described in detail later.

Formerly her dreams had consisted only of images of the motor, auditory and tactile types. A brief statement regarding her education during the past few years will serve now to substantiate the patient's assertion that previously she had had no visual imagination.

Up to the age of 13 the patient was looked on as being as bright as her associates. Throughout her college life, however, she was signalized by her roommate and family as having an exceedingly poor memory. English was particularly difficult. She was unable to remember eight or nine lines of poetry or prose, and then but for a short time. This much was accomplished only by tedious grind and repetition. History and geography were likewise very difficult. Interest was never taken in any of these. She could at no time picture to herself kings or battlefields, and mental images of cities and landscapes were unknown to her.

Mathematics was perhaps less difficult, but she never was able to visualize the problems. Her favorite studies were chemistry and biology, because, she explained, in these sciences she was able to see and use her hands in her work with the subject material. The solution of each problem, as it arose, was more a matter of physical exertion than a mental effort with abstract data. She liked the practical rather than the theoretical, the mechanical more than the literary.

In memorizing her work, a chemical formula, for example, she would start with one group and then reason out what the opposing groups should be. In drawing a structural formula she had no mental picture of it, but accomplished her task by remembering chiefly the movements of her hand. Her closest associate described her as "a freak all her life, lacking in some things and ahead in others, though never unusual enough to attract the attention of outsiders."

Taste and smell memories had always been keen—in fact, too acute at times, to the patient's discomfort.

Auditory images were frequent and distinct. Motor and tactile images as well were constantly good it seems.

About one and one-half years previous to her admission to the hospital the patient studied psychology. In the course of the class work she was led to scrutinize her ability in imagery. To her great astonishment she found that her classmates differed from her essentially, in that they could visualize and she could not. When told by the instructor to describe the mental images formed after the word "fire-engine," she enumerated only the sound of the gong, the clatter of the horses' hoofs and a rushing feeling. She could picture nothing of the horses, engine, men or streaming smoke. In recalling a flower, a rose for example, she recollected only "the feeling of smoothness against my cheek and the pricks from the thorns."

Drawing had always been difficult. In trying to sketch a maple leaf she remembered the sharp points of the leaf by the feeling of pricking and the general outline by the position of the fingers surrounding it.

In traveling her parents had noticed that she usually carried a collection of photographs. These were frequently inspected. The patient explains now that at no time was she ever able to recollect the faces of even her father and mother. In thinking of them she felt obliged to look at their pictures. For the scenes of her home she likewise had no mental imagery.

Novels, it seems, had very little attraction for her. She described them as dull and uninteresting, particularly the descriptive passages. Throughout her college life, at least, motor, tactile and auditory images appear to have played the most important rôles in memory.

These examples, corroborated by instructors and family, afford some idea of the subject's mental imagery during the several years preceding the cerebral operation. With the tumor extirpation the readjustment rapidly became apparent to the patient herself, first of all, and then to the examiners in charge of her. The development of the new type of imagery, moreover, was strikingly definite. Within a short space of time she could picture to herself flowers held before her, differentiating correctly the various shades and outlines. A book held before the eyes could later be visualized in all its details—binding, title, decorations, etc. A doctor, on leaving the room, was recollected in pictures of form, clothing and expression. Her pet dog, which had not been seen since admission to the hospital, was now pictured clearly, to her great astonishment and pleasure.

One afternoon when we entered her room together she enthusiastically exclaimed:

"Oh, I have had such a wonderful new experience! My nurse has just been reading a book to me. Let me tell you about it. . . . For instance, Miss M. was reading about a row of houses (description formerly bored her greatly, as noted before) which were so crowded together that they squeezed their bay windows out in front, and their living-rooms so narrow that they resembled parlor cars. I can see these houses with their bay windows perfectly now. And the parlors—why, I can see the car interiors with their rows of windows and their easy chairs, and even the dust on the window-ledges. Yes, I can see the colors perfectly." The images, however, did not appear to be overdistinct. Their intensity corresponded, apparently, more or less closely to the visual impressions.

### STUDY OF THE DREAMS

The psychologic development of this interesting case follows two paths. The first points to the past; the second points to the future. They both start from the patient's dreams. As has been mentioned, the night following the operation the patient had a vivid visual dream. That it was visual struck her with astonishment. At first she repeatedly said she could not remember ever having had such an experience before in her life. After several days of consideration of her newly acquired visualizing capacity, however, it was found that this first memory, or lack of memory, was misleading. She recollected that when she was about 8 she remembered seeing a girl with red hair on a bridge with a broken rail which sagged in the middle, and thinking at the time that she had seen it before. Since then she has "remembered" the occurrence, but could not visualize what it was about. She can remember visually very well now going to a shoe factory (before she was 8) and seeing the long bench on which the workmen cut out the leather. But she cannot visualize a "memory" of anything happening after that time. While she is unable to recollect actual occurrences of a visual nature since 8, she nevertheless can imagine, visually, persons and places which she must have seen. This is interesting from a psycho-physiologic point of view, since the patient's vision was always good up to the present illness, notwithstanding the fact that she had no visual memory or imagination.

The second path we wish now to follow concerns itself with the development of the dreams in significance and complexity. In her first visual dream the patient thought she saw her physician, a trunk and a gray wall. The picture was without color, other than being in black and white, like a photograph. It also had no action.

According to the Freudian theory of dreams, a dream is a symbolical manifestation of a repressed wish—it is a hallucinatory wish-fulfilment. Is that the case here?

Questioning the patient brought out the fact that she regarded her physician as her savior. She felt that she was rapidly approaching a fate, perhaps worse than death, and her one forlorn hope lay in this possibly successful operation. She said, "There was nobody I'd rather have seen than Dr. ——" (naming her physician). Several other associations must also have operated to bring a doctor to her mind. In the first place, her father was a doctor — the author of her being. In the second place, the physician to whom she had been taken for consultation diagnosed her condition correctly, and it was at his request that the operation was performed. Thus this image of her dream was at least triply determined by weighty determinants — weights having the significance of life and death, bodily and spiritually. Here another law of dream formation seems fulfilled, the law that single elements of a dream are overdetermined, that is, a number of motives unite to produce a single psychic effect.

The desire in this dream is undisguised. In this respect it is like the dream of a child. She wanted to see her deliverer and so she did. She wanted to go home and so she saw her trunk. Distortion comes in dreams only when what is wanted has to be concealed for social, ethical or other reasons. There was a slight repression, however, even here. Without this there might have been no dream. It is obvious that while she might properly desire to see the man who had saved her, she would have to repress that desire since he would be too busy to come merely to gratify her in letting her look at him. Thus here a slight ethical and social reason constrained the patient to repress her wish, which then fulfilled itself at no expense to any one, in a dream image. As a visualizer the patient was a child again, and dreamed like a child of just what she wanted. But as a visualizer she grew very rapidly, and, as she did so, her dreams grew more distorted, more obscurely symbolic and expressed more fundamental desires.

The second dream was somewhat more complicated, and in part a very interesting symbolical revenge. One of the doctors said she looked like a tomboy with her head shaved. She resented this a great deal, as she later admitted. She felt chagrined, she asserted, at having a man tell her she lacked in feminine attributes. That night she had her revenge. She dreamed that the offending doctor was a child, in a very lacy gown with lots of pink ribbons and bows. Here one is immediately struck by the increased complexity of the dream. It riots in color and form and has a conscious emotional content, which serves to distort it and thus to disguise its fundamental significance.

A number of possible wish fulfilments are manifest. The patient revenges herself against the offending doctor by making him look ridiculous. She also places him in her power where she can train him and make him do as she desires. In this way, perhaps, she can teach him better manners as he grows up. Again, in picturing a child she demonstrates to herself that she does not lack in fundamental feminine attributes and capacities. Again the dream is childlike in its clarity. Here manifest and latent contents are almost identical. A short conversation with the patient would convince almost anyone that she was the personification of the *ewige weibliche*. As many believe, the fundamental desire of such a woman is to have a child. Here the desire appears to be almost openly gratified, the only concealment being a slight displacement of affect. The element of ridicule is emphasized at the expense of the deepest desire—the desire for a child itself.

What is apparently the fundamental law of dreams, that is, dreams are wish fulfilments, is thus followed in both dreams recorded above. The law of dramatization is also exemplified, not only in these two dreams, but in all that follow. This law states that dreams are like pictures and that ideas have to be expressed dramatically.

The law of condensation—many motives being represented by one image—is satisfied here also. Thus the dream appears to be a compromise formation. The images selected are those which will satisfy at the same time many more or less divergent motives.

The next dream is far more complicated. The patient dreamed she was in a large house. When she entered the living-room, which was very large, she saw a group of people sitting before a fireplace. One was standing, a man, an intimate friend. For a moment she debated with herself as to whether she should show her real feelings or repress them because of the others present. She decided to act as she felt. She ran up to this man, greeted him joyfully, put her arms around his neck and kissed him. At this point she perceived the shocked look on the faces of the others, but she did not care. As he also did not appear to care, she took him by the hand and ran with him into the different rooms, all over the house. Then she awoke.

When the patient started to tell this dream, she hesitated. She finally said she would tell part. In the end she told all. The portion she intended to leave out concerned the kissing. The man was an old and most intimate friend. It grieved her because he had failed to inquire how she was, though he must have known about the operation. The day following the patient called out gleefully, "Do you wonder I wanted to hug him?" and showed a fat letter she had just received from the man of her dream. In this dream we see for the first time an excellent opportunity for the fourth law of dream formation to manifest itself, that is, the law of secondary elaboration. According to this law the dream itself is never so rational or consistent as it appears to be on recalling it. The dream is elaborated and rationalized in becoming sufficiently conscious to tell. One can never be sure how much of the final form of the dream is thus due to this factor. The first two dreams of the patient were severely simple. It seems highly improbable that there might be much elaboration in relating them. From the third dream on, however, the dreams are all so rich in material and so complex in form and significance that they give excellent opportunity for secondary elaboration.

Here we have a dream, furthermore, the hesitation in telling of which manifests a consciousness of the tendency to repression. The significance of the dream, as showing her affection and desire for the man, was not fully realized, although it certainly was partly felt. As the patient was not under obligation to endure psychanalysis no questions were asked. There is, of course, probably much more symbolical significance to this dream and to the dreams following than we can elucidate here. For any who may be interested in carrying further an analysis of this type the Freudian literature is recommended, especially Freud's *Traumdeutung*.

The night following the last dream cited the patient dreamed she was in a hole trying to get out. She took hold of a large stone—like a monolith—but it rolled over onto her, pressing her to the ground. It did not hurt her, however, and soon her "friend" (her dream lover) appeared and helped her out. Then she fancied she was on a street where there were a great many public buildings, especially churches.

For the benefit of those who may wish to try their hand at interpretation, the following dreams will be reported although no attempt will be made here to analyze them.

The patient was in a long and narrow room at night. The "friend" of her dream was there. She was on an operating-table having her nose examined with an ophthalmoscope. She could hear the doctors talking about her, but could not understand what they said. She was quite puzzled at their using an ophthalmoscope on her nose. She tried hard in the dream to find out what they were after. There were many doctors about and she could see them very distinctly. They all appeared to be quite unusual and peculiar in many respects. One in particular wore a very short beard. He looked extremely funny. The doctor had dark eyes, with quite conspicuous pupils, that is, the pupils were very large. The patient found these eyes interesting. At first she felt somewhat suspicious, but later they gradually gave her a sense of confidence. The nose was rather small, the features regular; she does not recollect the clothes. The first thing that the patient noted was the beard, then the eyes were seen, and finally the man as a whole.

The next night the patient dreamed she was coming from a room at the end of the hall. Near the stairway she met one of her college instructors. He presented her with some tea-leaves and asked her to make some tea. She descended some stairs, a long flight with winding railing. She saw the paper on the wall, the white treads, the mirror, and an old fashioned camphor chest, mahogany chairs, etc., exceedingly distinctly. Then she passed through her father's private office, seeing its details very clearly. On reaching the dining-room she found things rather muddled. It seems she could not accomplish anything. She endeavored to gather things together to make tea, but as fast as some were collected others disappeared. She saw a great accumulation of fancy and odd cakes. Some in particular were especially distinct. There were "platters and platters of things to eat."

In another dream the patient needed some sort of an operation on her ears. The operator was a man to whom she had been going for years for her ears. It was icy outside. She met a person whom she did not know, at first, though he looked familiar. She finally recognized him as a man her physician had taken into her room the day before. On the way to the office she went to her grandmother's house. Here she entered a brick-paved entrance hall different from anything she had ever seen before. Then she journeyed to the doctor's office. There were so many people waiting that they had to enter the inner office in groups. The patient was especially interested in one man with a child. "He had a rather sweetish type of face," she said, "and was tall and fair." The child was 3 or 4 years old. The man first spoke English, but fearing to be overheard he later conversed in German. She was much interested in him. Finally she entered the inner office, but the doctor was not there, and his son treated her instead.

After acknowledging that she had had a terrible recurrent dream, previous to the operation, which had stopped with the tumor extirpation, the patient could not be induced to tell its nature. She said it did not concern visual images, however. With this she asked to be excused from further questioning. The study necessarily stopped here.

One of the most interesting points relating to this series is the increasing complexity of the dreams as they appeared. It seems as if the dreams were being utilized for ever more and more significant symbolization. Simple gratitude and a desire to go home characterized the first dream, while love and marriage are symbolized in the later ones. It is interesting to note how dreams and visual imagination are probably in the service of the desires. Unfulfilled wishes of the day are satisfied at night by symbolic creations. The restoration of the visualizing capacity simply affords the person another method of presenting to herself her various wants.

It seems as though there must be some significance in the order of the dreams. First gratitude for her life appears, then a child, next a lover and then churches picture themselves in her dream-life consciousness. Is this not also the order of her real desires?

The problem of where the memory of the "lover" was before he appeared in the dream is very interesting. That the material, so to speak, was there for use in visualizing him, is proved by the fact that he had not been seen for some little time before the operation and not at all since. The image of the dream, therefore, must have been created out of material already present. Previous to the removal of the tumor, however, this material was not available either for dreams or visual imagination. Visualizing, perhaps, was actually done, at moments, but it was not sufficiently connected with the other thought processes constituting the ego-consciousness and so it was not remembered. Thus there apparently was some kind of dissociation between particular visual images and other images.

Regarding a possible physiologic explanation of this psychologic change in mental imagery we have little to suggest that is satisfactory. We know that functions of the various parts of the brain may be held in temporary abeyance, so to speak, by pressure—the so-called increased intracranial tension as well as the immediate neighborhood relationships. Following tumor enucleation, abscess drainage, and palliative decompressive procedures we are wont to expect amelioration of not only the headache, vomiting and lethargy, but also of the changes in memory, in attention, in emotions, and so on. What is more, we know now that the finer objective findings may alter rapidly in much the same manner. In cerebellopontine growths, for example—endotheliomas which may have no immediate connection with the cerebellum itself—where equilibrium and general muscle coordination are much disturbed, we are aware that often these symptoms may rapidly diminish in intensity following successful extirpations. A further demonstration is offered by the interesting charts which Dr. Cushing and Dr. Walker are gathering in a detailed study of the visual fields before and after cerebral operations. These show surprising enlargements of the form and color fields and increases in visual acuity, some changes even within twenty-four hours.

The rapid reappearance of visual imagery, then, as noted in this case, has clear-cut analogies in other aspects of cerebral pathologic physiology. Just why there should have been a selection for visual imagery alone, however, is not so clear. Auditory and motor images apparently showed no changes in intensity before and after the surgical treatment.

Starr thinks that the visions of delirium are probably produced by irritation of the visual area of the cortex. Irritation, we know, of the occipital cortex can produce forced revivals in consciousness of visual memories which may consist of actual images. More or less extensive lesions in the occipital cortex, on the other hand, are attended by losses of visual memories. While the endothelioma here occupied a parietal lobe site, it is conceivable that either neighborhood pressure or general tension factors may have inhibited, temporarily, this occipital lobe function.

We wish to express our gratitude to Professor Cushing for permission to investigate and publish a report of this case.

Peter Bent Brigham Hospital—30½ Shepard Street.

# HYPERTHYROIDOSIS OF INTESTINAL ORIGIN

J. C. HEMMETER, M.D., PH.D.
BALTIMORE

The pathogenesis and disarrangement of the internal secretions and defective coordination between these secretions and the nervous system which constitute hyperthyroidism or, when they are in an extreme state, Basedow's disease, are still veiled in obscurity. Whatever the internal disarrangement of a chemical or neurogenic nature may be, it constitutes, for the present, one of the mysterious problems of pharmacology, as well as of physiology and pathology.

When Basedow first published the symptom-complex in 1840, which has since retained his name, he described three classical signs as characteristic of this condition: first, exophthalmos; second, enlargement of the thyroid, and third, tachycardia. At present we could probably safely add two more frequent conditions. These are muscular tremors and disturbances of the gastro-intestinal tract, particularly diarrhea. The diarrhea has since then always been regarded as a consequence of Basedow's disease and I fail to notice in literature that anyone has reported diarrhea, or more precisely, any anatomic change in the gastro-intestinal tract as preceding the classical symptoms of Basedow. Robert James Graves, who worked over the studies of Basedow and confirmed them, nowhere states that a typical Basedow may follow years of gastro-enteric abnormalities. We have as yet no exact physiologic, pharmacologic or pathologic test for the existence of Basedow's disease in its incipiency—conditions which are more properly called "thyreoses"; when there is excessive function of the thyroid, the condition is called hyperthyreosis; when diminished, hypothyreosis. I should suggest a third idea where the thyroid secretion is not quantitatively diminished nor increased, but chemically altered into a secretion containing different chemical substances from the normal. I designate this as *dysthyreosis*. No one denies the facility of the diagnosis when the classical symptoms are pronounced, but usually when such a state of the various organs exists, there are already extensive pathologic changes in most of the internal organs.

In the present state of our knowledge we have principally two views which, though indefinite, might be stated as attempts to explain the internal disarrangement of the secretion of ductless glands and the disturbed reciprocal coordination of nerve-cells with these internal secretions. One is the view held by Moebius that the thyroid is at the bottom of the entire trouble. The other is not definitely associated with any clinician's name, but it is a view which maintains that the thyroid is only secondarily involved and that some other nervous or chemic deviation from the normal has preceded the thyroid abnormality. That pronounced cases of hyperthyreosis, even with exophthalmos and slight enlargement of the thyroid and tachycardia, have been observed where surgical removal of parts of the thyroid could reveal nothing abnormal in the gland itself, is suggestive of the possibility that the thyroid may be secondarily affected.

In a recent article[1] von Noorden describes remote symptoms of a nervous and muscular derangement consequent on intestinal disturbances and even goes so far as to suggest that his associate (Eppinger) has isolated a bacillus from the intestinal contents of such sufferers which is suspected of being the cause of the whole difficulty.

McCarrison's results are mentioned in THE JOURNAL[2] as follows:

> Having shown in the course of his researches on the etiology of endemic goiter that the infecting agent of this disease exists in the intestinal tract and that a plentiful amebic infection was present in this situation in the vast majority of all cases of goiter in Gilgit [India], McCarrison has been engaged in endeavoring to cultivate amebas from the feces of sufferers from this disease. During the course of this work he was struck with the constant character of the bacillary growths which appeared in the medium employed. This medium was the one recommended by Musgrave for the cultivation of amebas. The vaccine employed was, therefore, a composite one and contained organisms capable of growth on an alkaline and feebly nitrogenous medium. This vaccine was administered in selected cases in doses of from 150,000,000 to 350,000,000; the inoculations were made at intervals of from seven to ten days. The results obtained were most gratifying.

Recently Sasaki produced enlargement of the thyroid by feeding normal rats with feces of other normal rats, and he also produced thyroid enlargement by the subcutaneous injection of rat feces. These experiments are quoted from Julius Bauer.[3]

[1] Von Noorden, Carl: Intoxication Procceding from the Intestines. Especially Polyneuritis, THE JOURNAL A. M. A., Jan. 11, 1913, p. 101.

[2] McCarrison's Researches on Goiter, editorial, THE JOURNAL A. M. A., Aug. 10, 1912, p. 449.

We may interpret these quotations that intestinal abnormalities, though long recognized as a consequence of hyperthyroidism, may also be a cause, even if we limit ourselves to the conception that a live microbic agent is necessary to bring about this effect.

I wish to report three cases in which a chronic colitis of ten, eighteen and twenty years' standing had preceded the symptoms of hyperthyroidism. Two of these patients had been in Carlsbad for the relief of their colitis and one had been operated on, a partial thyroidectomy having been performed with only very transient relief of the symptoms. Naturally it would be desirable if we could find a method of determining when and how a colitis or enteritis is the cause and when it is the result of hyperthyroidism. Unfortunately, we are still lacking biologic and chemical tests for ascertaining the relation of these two states. I had personally hoped for such a test from the research of Dr. Reid Hunt, working in the Department of Pharmacology of the United States Public Health Department, but Dr. Hunt's acetonitril reaction has not proven of diagnostic help. I quote his own words from a letter to me:

> I do not think that the acetonitril reaction has at present any value for purposes of diagnosis; it does not seem to be constantly obtained even in marked cases of hyperthyroidism. I hope, however, it contains the germ of a method which may be developed into one of use.

Perhaps as important a conclusion as any can be deduced from the fact that treatment directed to the intestine is more efficacious than treatment by thyroidin, antithyroidin, or by Beebe's antithyroid serum, and in these specific cases even more effective than operation on the thyroid. When the original causative process is in the intestine, particularly in the colon, there is no treatment like lavage of the colon with irrigations of 1 per cent. solutions of ichthyol. As much as 1 liter may be used in persons having a large colon and half a liter in persons with a small colon. I have also found that the *Bacillus bulgaricus* in pure liquid cultures administered for a long time reduces the tremor, as well as the headaches and insomnia.

I hope to furnish a more complete report when the cases which I still have under observation are more carefully studied. Treatments of various kinds had been administered in all three of my cases. One patient had gone through a rest-cure of ten weeks with electric, dietetic and medicinal applications. Another had been in a sanatorium for two months and had taken bromid of quinin and ergot for six weeks, with varying effects. Both of these had taken antithyroidin, but never were free from headaches, insomnia, tremors and tachycardia except when at perfect rest. Whenever they resumed their duties their symptoms returned. I kept them in bed three weeks, also, but on a meat free diet and colon irrigation and symptoms gradually abated. One patient at the date of this writing has been free from headaches, tremors, and insomnia for six months, though at times he still experiences tachycardia if he exerts himself in warm weather. A second patient has had no tachycardia that she knows of for a year, sleeps well and appears normal, excepting an occasional attack of diarrhea, which has been traceable to errors of diet. The third patient is still under observation, but is progressing so satisfactorily that, although he is a busy physician, he has had only one attack of tachycardia in nine months while attending to his professional and scientific work.

| | | Average Pulse |
|---|---|---|
| Case 1. | Before treatment | 120 |
| | Last six months | 78 |
| Case 2. | Before treatment | 106 |
| | After one year | 80 |
| Case 3. | Before treatment | 100 |
| | Last four months | 74 |

I still advise continuance of cool needle-spray douches, strict diet, twelve hours' rest a day and one colon irrigation every six to ten days in these patients. One patient, however, has not resumed irrigation of the colon for five months and has remained sufficiently well to attend to his work. When we remember how unpromising purely internal and physical treatment of the thyreoses has been, these results of this special therapy are sufficiently favorable to warrant a continuance of it in the special types of thyreoses in which it appears indicated.

Further studies will be made to throw light on the ideas held by McCarrison, von Noorden and Sasaki, namely, to determine whether a specific microbic inhabitant of the colon is either directly or indirectly the cause of this special type of thyreoses. The chemical and bacteriologic character in all of the evacuations of these cases—I mean the study of the feces—will be reported in a future communication. But I may premise my future report by stating that no specific bacterium or protozoon has been discovered by us that enabled us to reproduce successfully the Basedowoid symptoms and signs experimentally on animals.

Read and Charles Streets.

# EFFICIENCY IN NURSING *

W. GILMAN THOMPSON, M.D.
Professor of Medicine, Cornell University Medical College
NEW YORK

This title is intended to describe the much-neglected field of the economic side of ward nursing, especially in the larger hospitals. Recent magazines are filled with articles discussing "efficiency" in laying bricks or handling tools, and "get-together" principles are the order of the day, but one looks in vain for any serious discussion of the importance of efficiency in the nurse's routine or any "getting together" between the architect who plans the clothes closets, pantries and other ward accessories and the nurses who have to walk endless miles between them in the course of their routine work. Mr. Taylor has shown us how many unnecessary motions the bricklayer makes—how often he bends his back and moves his arms to lay a single brick. Does any one know how many unnecessary steps the ward nurse takes or how often she bends her back or lifts heavy weights? What we do know is how tired and worn she gets when the service is heavy, and how many hospitals, from various causes, have inadequate nursing service, whereas a little intelligent direction would save enough energy in the aggregate to amount to the services of several additional nurses.

Having for some time had opportunity to observe these problems in several large hospitals, both municipal and privately endowed institutions, I finally began to gather statistics. In stating them I shall purposely omit names, in order to avoid the implication of any personal reflection. As I have been unable to find reference to any such facts elsewhere, they will be given in some detail.

---

[3] Bauer, Julius: Fortschritte in der Klinik der Schilddrüsenerkrankungen, Med. Klin., 1913, No. 5, p. 146.

* Read in the Section on Hospitals of the American Medical Association, at the Sixty-Fourth Annual Session held at Minneapolis, June, 1913.

I first tried having the nurses wear pedometers in several hospitals. In one I found that the day nurse walked seven and one-half miles a day, in others an average of five and one-half miles. This, in addition to all the stooping and lifting the nurse has to do, besides carrying heavy weights, involves an excessive expenditure of foot pounds of energy. In one hospital in which the wards are so long that the furthest bed is 120 feet distant from the ward kitchen tables, it was the custom to carry the food trays separately to and from each bed three times a day. When all patients were bedridden, as often happened in the twenty-six beds, it was a matter of simple addition to show that some one, usually a nurse, had to walk two miles per ward each day merely to serve meals! The very heavy wooden trays were found to weigh 8 pounds each, and when loaded with heavy ward crockery and with food and drink each tray weighed 15 pounds. Some one, therefore, in each ward had to haul a considerable weight two miles. An additional consideration was the minor factor of so much parading up and down a ward where quiet should be an essential in the treatment of the very ill. I suggested obtaining wheel trucks adapted to carry a dozen or more trays at a trip. I was met with the objection that "the food would reach the patients cold." At this I was surprised, as such trucks are in use in some places, although many large hospitals are without them, partly, no doubt, because no one ever suggested to the architect that he provide space for them when not in use. Experimentally, therefore, I took a common wheel stretcher, placed eight trays on it and, watch in hand, compared the time of delivery with the serving of a like number of trips individually. The entire time consumed in serving eight patients and returning to the kitchen was only two minutes with the truck and ten minutes without. This disposed of the cold-food theory. The distance traveled was 74 feet as compared with 240 feet. Since that time trucks have been used and the comment which reached me from a ward maid, who in this case assisted in the meal service, was: "Bless the man that invinted thim thrucks—sure the corns is all gone off me hands since." The wooden trays had absurdly high backs, so I had two pounds of wood sawed off from each tray.

The bed screens weighed 31 pounds, and three were required to surround a bed. In accordance with the deep-rooted objection common to many training-school superintendents to accumulating anything in the wards intended to promote the true comfort of the patients, these screens were stacked in the hall when not in use. If a man in the furthest bed had to use a bed-pan, some one had to haul a weight of 93 pounds to and from him and then, of course, carry the bed-pan to and fro, thus walking in all about 480 feet. After some insistence I succeeded in having some of the screens left at the distant end of the ward, where they would be reasonably at hand when needed.

In the books on physiology and therapeutics it is taught that water is a good diuretic and promotes activity of secretions, lessening constipation, and some of the more thoughtful of us advise patients to drink it between meals! How many hospitals have drinking water at hand in the wards? In one hospital I found that a few water-coolers in use in July and August were all stowed away by the nurses for the winter in a storeroom in the attic because the Powers that Be thought that they encumbered the ward and, besides, the poor thirsty patients sometimes spilled a little water on the floor! Of course a thirsty man may call a nurse to bring him a glass of water when she is not too busy, but if she has to walk a block or two to get it, she is not likely to do it very often. To show that this is no exaggeration, I went into a tuberculosis ward where the faucet and the pantry and the patients were all in widely separated localities. Here the tumbler had to be taken to the faucet for disinfection and then replaced on a very remote pantry shelf. I asked a nurse to make believe a patient was thirsty and get him a drink. I followed her around, pacing the distance traveled, and she walked 364 feet. At this institution the trustees finally ordered water-coolers in each ward and an individual tumbler to be kept accessible for each patient. It is noteworthy that such suggestions never come from the training-schools.

There is usually a single table at one end of a long ward to which the nurse periodically carries the bedside note-blanks to be written up several times a day. How many feet of useless tramping would be saved by having a second table in the center or opposite end of the ward! The patients' bedside tables are all placed on the same side of the bed, regardless of the fact that one may have hemiplegia and be unable to reach the table with the unparalyzed arm.

There is a very good municipal lodging-house for tramps in New York City. In most large hospitals the medical wards are precisely like the dormitories of this lodging-house. There is a bed, a small table, and a more or less (usually more) uncomfortable chair for each person; nothing else is kept in the ward or within easy access to make a patient *comfortable* in bed. There are no cranes at the head of the bed for a heavy patient, or a stiff-jointed one to pull himself up by, or for a heavy, fat patient to lift himself easily on to a bed-pan. Inquiry usually shows that if there are any in the hospital "they are over on the surgical side." The nurses (or rather their principals), do not like them because they detract from the symmetry of the ward. There may be a few back-rests, but the best kind, which collapse when not in use and are permanently fixed to the head of the bed, are seldom found. In one hospital I discovered that portable rests were stored in a remote closet so far away that the nurses seldom had time to get them. I insisted on having them hung on hooks behind the beds. When I left the rests did also! Often a convalescent is able to sit up only long enough to eat a meal, which he does in comfort with a back-rest, but what nurse has time at the meal hour to walk a block and bring in a heavy rest to be used only a few minutes and then take it back? How much simpler to set the dinner tray flat on the patient's stomach and let him try to eat lying flat and getting more and more tired from the weight (for not all trays have legs and, when they do, they are usually too short)! If one's appetite is poor, discomfort while eating certainly does not improve it.

How many medical wards have cradles to take the weight of the bed-clothing off from swollen, rheumatic leg-joints? Ask the nurse, who says she "has heard of one in the building but it must be over on the surgical side." Her rule is to strap the bed-clothes so tight over the feet that they cannot slip, and the patient, in consequence, enjoys a more or less painful talipes equinovalgus. I produced a decided sensation in one hospital. A 300-pound woman with nephritis, incontinence, bedsores and high tension came into my wards. When lying on her back she was 28 inches across at the hips and she lay on a 32-inch-wide bed. She could not turn without landing on the floor. She needed to be turned for enemas, to have her sores dressed, and to be cleaned after incontinence. She needed hot packs. In this hospital of 1,000 beds there was not *one* for an unusually obese patient or an unusually tall one. I sent in a requisition for a 48-inch bed. A hurry call went to a department store, and the bed arrived, but was so low that the nurses were breaking their own backs in trying to relieve the patient. So we propped it up on shock blocks and the patient was finally able to turn herself without risk of breaking her bones by landing on the floor. This apparently simple innovation was regarded as so remarkable that nurses came from neighboring wards to see it!

Such an arrangement as a foot-rest to keep a patient from slipping to the foot of the bed, or to brace against while sitting in bed, is so serious a departure from training-school routine orders as to the "looks" of the bed, that, although I have ventured to hint of it, I have lacked the moral courage to insist on it!

There are many patients who cannot use bed-pans with satisfactory results. The very obese, for example, cannot. Yet very few wards are supplied with the convenient portable commodes which are mounted on casters, and when they are I find the nurses, for some reason, very reluctant to use them, although their use requires no more work and no more screens than that of bed-pans.

There are many patients who are old, feeble, or mentally dull, or mildly delirious, who in turning in the narrow hospital bed may land on the floor, unless protected. All they need is a couple of boards at the sides of the bed, fastened by tying them through holes bored in the ends. But the nurses find it easier to fasten draw-sheets over them. This method restricts freedom of motion and irritates, and I have occasionally seen a victim so tightly fastened by a sheet drawn across the chest as to have serious impairment of breathing. I do not, of course, refer to the actively delirious who attempt to get out of bed unless restrained.

All these appliances require a little thought for their use, and my experience is that unless they are kept within convenient reach they are never used, yet they add enormously to the comfort and welfare of the patient in bed. The architect usually has never thought of them and makes no provision for space in which to keep them when not in use.

There are many other details concerning efficiency, as, for instance, lack of system in the method of distributing the various things for the morning toilet, distributing medicines, etc. There should be more ward tables than are generally found. They save many steps and promote efficiency of service. The visitor has nowhere temporarily to lay a hat or heavy coat, unless he puts it on the patient's bed or on the floor. Convalescent patients need access to a table on which to lay a book or a checkerboard, if they are ever permitted anything to divert their minds from their own or their neighbor's ailments.

I do not think these suggestions unreasonable, nor do these appliances for the comfort of patients necessarily detract from the appearance of neatness of a ward, yet the modern training-school attitude is so increasingly pedagogic and so decreasingly humanitarian that I am unable to recall a single suggestion originating with the officers of a school designed to promote the comfort of patients in bed, and I know of more than one school in which nurses are reprimanded for following their natural impulse to favor the individual. I have sometimes doubled a pillow temporarily to ease the position of a dyspneic patient, the nurse telling me she did not dare to do it herself. I admit that in general the window-shades should be kept on the same level, but if a patient has conjunctivitis, photophobia and a severe headache from facing a glare of light, and the nurse dares to pull down the shade opposite, she is liable to severe reprimand. Yet in private practice, if she refused to regard the comfort of the patient in such matters, she would quickly be superseded. Lectures on bacteriology, urinalysis, voice culture and the functions of the ductless glands loom large in the up-to-date training-school curriculum, but the gentle art of making the ward patient *comfortable* in bed, is not only unpracticed but actively discouraged in many instances.

To return to the problems of nursing efficiency. Physicians themselves are often lacking in its consideration. On "rounds" nurses are kept waiting while learned bedside discussions are held over polymorphonucleosis or complement deviations, when the service is heavy, and they ought to be serving a glass of water or easing an aching limb. The doctor's routine often calls for the recording of pulse, temperature and respiration data every three hours of every patient in the ward, although perhaps not half of them require it more than two or three times a day, and some few may not require it at all. This is notably the case on the surgical side. Now three minutes per patient to take these observations, including disinfection of thermometers and writing down the three records, is a minimum time allowance if any approach to accuracy is to be expected. In a ward of twenty-five patients, four observations a day at three minutes each, requires 300 minutes or five hours. But no nurse spends this time over such work and it would require her to neglect urgent matters if she did. Is it not better to order fewer records and have them reasonbly accurate?

One great difficulty in relation to the doctor's efficiency arises from the almost purely American custom of rotating services. Whatever may be the merits of this question, which cannot be discussed in this paper, every service should have its administrative director, that is, one physician or surgeon who is continuously responsible for securing uniformity and continuity in the matters under discussion. If back-rests and cranes and drinking-water and bedside boards and tables and food-trucks and commodes and foot-rests and leg-cradles and similar appliances are admittedly useful adjuncts to treatment and comfort of patients, they should not be brought into requisition for two or three months while Dr. Jones is on duty and then hustled into oblivion the moment Dr. Smith succeeds him, who is not regarded by the school authorities as a simple-minded crank, always trying to make patients comfortable instead of giving them an excess of pills and potions.

I have heard certain extremists among those seeking to regulate the training of nurses advocate an eight-hour system of ward work, although I have heard no definite statements as to where the additional funds were to come from, which such a system would entail, or how the additional housing required could be obtained. Nor have I heard any facts presented as to the health of women as affected by their hospital course of training. Such facts, indeed, I find are not easily obtainable from training-school records. In one large hospital, however, where the work is so arduous that the health statistics of the nurses may be regarded as showing the extreme to which their energies may be taxed, I obtained the following data:

Total number of nurses in the school—119.
(All of these nurses were ill for at least one day.)
Total number of working days in 1912—41,650.
Total days of illness—583.
Percentage of days of illness—1.5.

Among the illnesses were eight cases of scarlet fever, seven of diphtheria, three of measles, one of typhoid fever and three of German measles, which collectively account for 433 days of the 583. As these infections were not, strictly speaking, due to overwork, it is fair to deduct the nineteen nurses having acute infections from the total of 119. This leaves 100 nurses with only 150 days of illness, or an average of 1.5 days of illness per nurse for the entire year. It thus appears that the average is extremely low, and compares very favorably with similar statistics of any large group of young working women, as, for example, factory employees, although the working hours of the nurse were between ten and twelve, as compared with the eight or nine of the factory employee.

In conclusion, I would make an earnest plea for the study of greater efficiency in nursing in order to conserve the nursing force which we have in any hospital, and for the greater use of common-sense appliances for promoting the comfort of patients in bed.

If the nursing system of to-day is being overweighted with theory and pedagogy to the detriment of more legitimate practical and humanitarian aims, which unquestionably is true, physicians have no one to blame for it but themselves, through their lack of cooperation and increasing tendency to permit training-schools to be managed by extraneous influences, manipulate their own curriculums and arrogate the responsibilities which are primarily the function of the doctor.

34 East Thirty-First Street.

# THE TRAINED NURSE OF THE FUTURE *

RICHARD OLDING BEARD, M.D.
Associate Professor of Physiology, University of Minnesota, College of Medicine and Surgery
MINNEAPOLIS

With the ever-extending specialization of modern society, certain social groups take on the character of human commodities. They do not produce, but they conserve values. To these groups, the profession of nursing women belongs.

These human commodities are created, in the course of social development, by the need for personal service as between man and man and by the demand that this personal service, in degree of the exigency of human need, shall be of expert quality. Some particular agency of social service is frequently employed for the immediate supply of such expert assistance. In the case of the trained nurse, the hospital has served as her creative agent. Not unnaturally, the agent of creation becomes or attempts to become the maker and the molder of the thing created; and not infrequently it comes to regard the creature it has incubated as its own particular perquisite, and designed specifically for its own use. This proprietary relation, the hospital, as the foster-mother of nurses, with the exercise of something of the maternal instinct and with more of the exercise of the instinct of self-perpetuation, has endeavored to assume.

But somehow or other in the unfolding of the biologic plan, the human creature tends to get away from his creator, to say nothing of his inevitable assertion of his independence of the parental agent of his creation. And what is true, as a matter of biologic development of the individual, is true of the group. No social condition of the group can be ultimately fixed, no economic principle of its service can be permanently established, in the fixation or the determination of which the welfare of the group and of all the parties in interest in the life of the group has not been fully and fairly considered.

In the segregation of this group of human commodities which constitutes the profession of nursing, there are four parties in interest: first, the public that it serves; second, the hospital system that it serves; third, the medical profession whose essential handmaid it is, and fourth, the group of nursing women itself. Since the greater includes the less, it would seem that the problem might be reduced to simpler terms; to two factors, indeed, society and the nurse. But in a society so highly specialized as our own, interrelational group interests arise and, therefore, in the present instance, it is essentially a four-factored equation with which we are forced to deal. Perhaps no other group of human commodities has to sustain so many relationships in its service as does that of the trained nurse. At the present juncture, each one of these relational factors is seeking to exercise a dominant influence in the development of this human commodity group. Social welfare societies, hospital associations, medical associations and nurses' federations are all busy with the question of the graduate nurse.

So vital and yet so unseen is the force of the social movements which express themselves from time to time in what we term public sentiment, that they are hard, indeed, to reckon with. In America, public sentiment is a force which finds expression slowly. It has taken the public a long time to learn the values of the trained nurse as a social commodity, as the agent of an important social service; a tardiness to be traced to the fact that nursing is only a differentiation of domestic duty. But there are many evidences that the public is beginning, not only to appreciate, but to utilize, in many different directions, the services of the nursing profession, and that this type of human commodity is a definite answer to a very definite social demand.

The most actively dominant of all the parties in interest in the development of this social group has been the modern hospital, and hitherto there has been adequate reason for its influence. It has been the sole agent of the production of the trained nurse; it has created and controlled the opportunities of training. The product of its early efforts represented new and real social values, as contrasted with the nurse of earlier days who, like Topsy, was a social orphan and "just growed."

The profession of medicine, which has been simply the co-employee, with the nursing group, of the hospital of the past, has exercised but an advisory influence over the birth and training of the nurse. It has been the habitual critic of her development, and very pertinently so, because the physician is ultimately the only competent judge of the fitness of the nurse and the chief sufferer, held responsible to her employer, the patient, for her

---

* Read in the Section on Hospitals of the American Medical Association, at the Sixty-Fourth Annual Session held at Minneapolis, June, 1913.

possible unfitness. Yet as a purveyor, only, of the nursing product of the hospitals he has had to take, and often to train anew, just what he could get at their hands.

Up to a very recent day this human commodity, herself a social unit, not forming until lately into a definite social group, has been the most helpless and, often, in the measure of her own unfitness, the most hopeless factor in the evolution of her own class. Invited into a newly made calling, poorly prepared for her responsible undertaking, often imperfectly trained in its essential duties, hurriedly pushed out into an alien world; a half-baked social product, thrust into the fulfilment of an uncertain social need, it is small wonder that she has had a hard time finding herself. The instinct of the eternal feminine for sacrificial service has been her sole saving grace, the guiding light of her star of undoubted destiny, leading her on to the realization of her important social function.

Suddenly, as human progress goes, this group of human commodities to which she belongs finds itself in large, active and growing social demand, and with the growth of that demand, the relation of the several parties in interest, in the process of the development of the graduate nurse, has undergone a radical change.

Primarily created in answer to the demands for hospital nursing, the service of the graduate nurse has extended readily to the private homes of the well-to-do; but of late it has gone far beyond this limited range of usefulness. Trained nursing has come to be regarded as a utility which should be secured for the uses of all classes of the people. Its field is widening out beyond the lines of a purely personal service into the broader range of social service in many and varied forms.

To-day trained nurses are in the offices of physicians, assisting in the care and ministering to the comfort of temporary patients and in the conduct of private laboratories. They are becoming the professional aids of the doctor in his daily duties.

Trained nurses are in the public schools, and rapidly the system of health inspection is extending from larger to smaller communities. Here, as in the doctors' offices, graduate nurses serve as the immediate assistants of medical officers; they reach the homes of the children, become the sanitary advisers of their parents and are definitely engaged in bringing the principles of preventive medicine within reach of the practice of the people. In private schools and colleges and in state universities, they are appointed as residents in charge of the health and ill health of women students.

Trained nurses are employed in the great service agencies of relief in the large cities of the country. The badge of the visiting nurse, devoting herself to the sick and the suffering in the homes of the poor, is no less a mark of honor because it is coming to be a common one.

Trained nurses are becoming the effective agents of the constructive work of great philanthropic enterprises concerned with the problems of child-welfare, the prevention of infant mortality, the study of mental hygiene and the control of tuberculosis. They are employed in the hospital service of the army and navy and in the Red Cross Society throughout the world.

They are going far into the field of missions, both at home and abroad, and are ably supporting the efforts of medical missionaries.

They are enlisting in the welfare work in great department stores and manufactories, where an enlightened management finds an economic asset in the health and happiness of its employees.

Trained nurses are at work in the free clinics of city dispensaries and are doing valuable duty in the social service departments of the great hospitals.

Everywhere they are the effective agents of scientific medicine; they are putting principles into practice and are filling in the great gap between the laboratories of the schools and the common life of the people.

With this widening out of its field of private and public usefulness, with the opening up of its opportunities of social service, it is inevitable that the profession of nursing should have awakened to a strong sense of class or group consciousness—that it should be seeking eagerly to come into its own, as the determinant of its own welfare, the exponent of its own needs, the arbiter of its own relations to the hospital, to the profession of medicine and to the public it serves.

The development of this class-consciousness is distinctly shown at four points of social movement:

1. In the demand for legislation creating state boards of examiners to regulate the practice and to legalize the practitioners of nursing. While here, as in the profession of medicine, this demand begins with a desire for protection on the part of the profession itself, such laws, in their operation, are an exercise of the police-power of the state for the protection of the people from the incompetent. They may be taken as an acknowledgment of the relation of the nurse as a social servant in the state, whose capacity to serve, in a calling which involves the health and the life of its citizens, should be attested by the license of the commonwealth.

2. In the movement, inspired by educational leaders of the professions of nursing, toward the standardization of the education of nurses in America. This movement, to be undertaken by the Carnegie Foundation for the Advancement of Teaching, contemplates the study of conditions in six or more states of the Union, for the purpose of reaching some consensus of judgment in the matter of entrance requirements, preliminary training, duration and character of courses, etc. If the Foundation shall accomplish for the profession of nursing, in any substantial measure, what it has achieved for medical education in this direction, it will do society at large a notable service.

3. In the recent rise of university schools for nurses. The University of Minnesota is the pioneer of this significant movement for the better education of nursing-women. In creating a school for nurses as a department of teaching, under direct university control, in charge of the faculty of the medical school and affiliated with the teaching hospital, which is similarly owned and controlled by the university, it has led the entire world, although it has been happily followed, already, by two neighboring state universities. The significance of this movement lies not alone in the high standard of training which the university has set, but in the fact that its action tends to remove from the exclusive control of the hospital, as such, the education of the nurse. Its significance can be measured only by those who have studied the problem of the education of nursing-women from the point of view of the interest of the student in training, apart from the interest of the training hospital. The guarantee which the university gives that the student's educational interest shall be paramount and that the pupil-nurse shall not be exploited for the benefit of the hospital service sounds the note of an emancipation which could not be effected, perhaps, by any other agency.

The essential features of the university curriculum for nurses may be of some interest. The diploma of a high school of the first grade and an actual examination to determine the physical fitness of the candidate, conducted by the physician of the school, are requirements for admission. Preference is given to women of superior attainments. A preliminary course of four months is required, during which the pupil is not in hospital residence, for which course she pays a tuition fee, and which covers instruction for from six to eight hours daily, conducted in the laboratories and lecture-halls of the university, in the subjects of anatomy, physiology, bacteriology, chemistry, materia medica, English, penmanship and lettering, physical culture, hospital economics and practical dietetics—a course with which the student is exclusively occupied during the four months, thus relieving the period of subsequent hospital service of many wearying hours of evening lectures. The superior fitness of the hospital entrant for her practical duties, by virtue of her preliminary course of study, has proved itself clearly to those who are in immediate charge of the school. A two months' probation service in hospital, followed by two and one-half years of graded service and study in the wards of the hospital and the outpatient clinics, complete the course. An eight-hour hospital day and the employment of an adequate number of graduate nurses as long as may prove necessary for the proper conduct of the school are added features of the university plan. On recommendation of the medical faculty the university degree of Graduate in Nursing is conferred by the Board of Regents.

4. In the recognition that the time has come when the gauge of fitness to teach and to train students in nursing must be applied to the hospitals. A demand for the educational standardization of hospitals is making itself felt.

In the past twenty-five years the number of hospitals engaged in the business of making nurses, in the interest, primarily, of the hospital's own economic salvation, has increased to the point of real educational danger. A scarcity of matriculants, low standards of admission, overworked pupil-nurses, a deteriorated and inadequately trained output, a surplusage of graduate nurses in private practice in many communities, and a lessening of earning power in consequence of this overproduction are the inevitable results.

The scarcity of nurses, of which so much has been heard in recent years, is a matter of real famine in the quasipublic and private hospitals, which, under denominational or individual control, have been unduly multiplied. It is not a matter of famine of trained nurses in private practice. If there is any scarcity of nurses beyond the graduating lines of the hospital, it is in the higher vocations to which the practice of nursing leads. These hospitals which, like the overnumerous denominational churches of most communities, are rarely filled, maintain training-schools for nurses as a necessary condition of their own support, divide and subdivide the educational field to its serious detriment, and care for their patients at the cost of the labor of their pupils. Their precarious fortunes are, in no small part, dependent on their attracting student nurses. Even at that, these quasipublic and seldom free hospitals fall back continually, under the plea of a charitable function which they do not fulfil, on subscriptive support to make up their annual deficits. Were these hospitals compelled to employ graduate nurses and to abandon their training-schools, some of them would speedily close their doors. Undoubtedly, those which could survive would eventually be better served.

The results of this uneconomic multiplication of hospitals and, along with them, of training-schools for nurses, are seriously felt in many of the larger institutions, which are compelled to supplement their force of pupil-nurses by the employment of graduate nurses, for which the private patient has to pay as much as he would for similar service in the home. Many of the best nurses now prefer hospital practice to private employment and naturally cultivate these opportunities.

The practice, in itself, suggests a remedy for the present educational misfortunes of the training-schools. The smaller private or special hospitals with less than an average daily complement of thirty patients (not beds) should be debarred, by law, from the maintenance of training-schools, for which their service is inadequate. The conduct of standardized training-schools should be confined to general hospitals of standard capacity and equipment. Substandard schools in special hospitals should be forbidden the graduation of nurses, but should be affiliated with standardized general hospitals, which should receive and credit their matriculants with equivalences of time and service and should graduate them when their full complement of training is secured. Direct affiliation with or ownership by recognized medical schools should be a prerequisite in standardizing the teaching hospital. The schools for nurses should be under the direction of the medical faculty or should have a special faculty affiliated with the medical school, on which a number of medical educators should sit. Since the day is coming when all medical schools will be university schools, it will naturally follow, if this relationship is established, that eventually the schools for nurses in America will also be under university control. Let us speed the day!

No substantial progress can be made in standardizing the education of nurses until the commercial value of the nurse to the hospital is eliminated from the question. That it will be eliminated and that progress will be made are assured by that essential fitness of things which ultimately rules the acts of men.

In discussing the trained nurse of the future, it is not necessary to conjure up any visions of a distant day. The consummation of events which are now in progress must lead up to practical results in an immediate to-morrow. There are great and difficult problems before the profession of nursing, but it is going to realize itself in their practical solution. To standardize the hospitals which conduct training-schools; to standardize the teaching of the schools; to standardize their product by effective state regulation of practice—these are large and serious undertakings. They will require the combined wisdom of the leaders of the profession and of their natural allies in the profession of medicine.

To equalize the social availability of the trained nurse is one of the most momentous matters with which the profession of nursing has to concern itself. At present, between that part of the public that can comfortably pay the fair wage of trained nursing and that part of the public which receives or should receive its trained nursing through the medium of organized relief, there are large classes of the people who are altogether unable to meet the expense of such service or who, meeting it, are financially disabled by the drain on their meager resources.

The proposed training and graduation of women of less adequate preparation, to be known as "nursing assistants," etc., and to work for lower wages, is no real solution of this very serious problem.

The plan evolved by a committee of the American Hospital Association and presented by Dr. R. H. Babcock of Detroit is an ingenious attempt to meet the similar college connections. The University of Minnesota has gone a step further and has university education and university control of the training-school of its hospital.

Teachers' College of Columbia University has an endowment of $150,000, established for the department of graduate work for nurses.

For the smaller hospitals with suitable affiliations to insure good general practical training, there has been suggested the possibility of combinations of two or more hospitals to share the expense of securing instructors in the sciences, these teachers to give the same courses in each hospital.

Technical high schools are increasing in number, and courses in fundamental nursing subjects have been established.

A course in dietetics is given in the Springfield (Mass.) technical school. The technical high school of Toronto gives a six months' preparatory course in nursing. For the hospitals that are unable to meet high standards for training nurses there is a field too little developed, that of training attendants. The Special Training-School Committee of the American Hospital Association, which reported at the annual meeting in 1909, recommended that attendants be trained "in hospitals too small to maintain a training-school, in chronic wards of large hospitals, in special hospitals and homes for incurables." There should be, however, no confusion between the trained nurse and the trained attendant.

Physicians and the public should be made to clearly understand the difference in training; otherwise, with attendants failing to meet responsibilities which should only be given to graduate nurses, much harm will be done to the present standing of the nursing profession. No hospital should undertake the training of attendants without an adequate staff of trained nurses to provide good nursing for acute cases and to assume careful oversight and instruction of the pupil attendants.

That the demand for attendants will exceed the supply for a long time to come, I am thoroughly convinced. It is not alone the poor who will be benefited. Many well-to-do people who are suffering from chronic diseases can be well taken care of by those who have been trained in the mechanical work of nursing.

Finally, let us accept the fact that training-schools for nurses should be able to provide adequate theoretical training and practical experience. Let us make this clear to our hospital boards and benefactors, that the necessary money may be spent on our nursing departments.

Massachusetts General Hospital.

---

## ABSTRACT OF DISCUSSION

### ON PAPERS OF DRS. HOWLAND, BEARD AND THOMPSON

**Dr. P. E. Truesdale**, Fall River, Mass.: There are many problems yet to be solved bearing on the education of the nurse. Her proper training and an efficient care of the sick must be accomplished simultaneously and harmoniously. The fact should not be lost sight of, however, that hospitals are founded and should be maintained for the sick. In America, particularly, this attitude is in a large measure responsible for the favorable impression which our hospitals have made on the public. If the education of physicians and nurses is to be made a paramount issue in hospitals, charitable or pauper institutions only will exist.

I wish to ask Dr. Beard what his results have been in the employment of graduate nurses for hospital work. In my somewhat limited experience I have found that the graduate nurses who seek hospital work are of two types; one represents the highest type of nurse; the spirit which prompted her to enter the nursing field was one of unselfish devotion to the afflicted. Her reasons for preferring hospital service are genuine. She makes the ideal nurse and accomplishes vastly more in the hospital. The other type is at the other extreme. She is available most of the time, and will take private work or hospital work as it happens to come. She has her diploma, and now cares only for a salary. It is always a risk to give her responsibilities, and her sense of discipline is a thing of the past. Yet a hospital superintendent who employs graduates only must content himself with a majority of this class and he and his patients should command your sympathy.

Dr. Howland sounded the keynote when he stated that smaller training-schools must meet the requirements by affiliation. It seems to me that Dr. Beard, Dr. Howard, Dr. Howland and other authorities on the education of nurses should indicate the standards of education to approach, and those training-schools which are found wanting should be counseled and reorganized instead of condemned.

**Dr. Arthur B. Ancker**, St. Paul, Minn.: The City and County Hospital of St. Paul was the first to establish a training-school in this section of the country. We started out with a two-year course, and succeeded in graduating a good many young women who have successfully practiced their profession, several of them obtaining distinction. Furthermore, it has been my observation that some of the most ardent advocates of the three-year course are themselves the possessors of diplomas that they obtained after two years of training. If only because of the advantage that accrues to the hospital, I would advocate the three years' course.

A high school or a university education, as a qualification for admission to the training-school, is desirable, but I do not believe that, primarily, it is the most important consideration. If the candidate have a good home training, industry, and ambition, something less than either of the other qualifications would do.

In the twenty-one years of the City and County Hospital Training-School for Nurses we have had but three deaths, one from typhoid fever, and two from scarlet fever. I cannot remember one of our nurses who, when she had secured her diploma, had to abandon her career because of her physical unfitness.

**Miss Louise M. Powell**, Minneapolis: I should like to give one experience at the University Hospital to show that high standards can be maintained even though it costs a good deal of money. In the fall of 1912 we had a hospital of 120 beds to open, with fifteen pupil nurses. Instead of throwing down the barriers of our high-school requirement and preliminary course and working our nurses twelve hours, the faculty gave us permission to employ as many graduate nurses at fifty dollars per month as were necessary to carry on the work of the hospital. We employed, for a period of from six to eight months, twenty graduate nurses. I agree with Dr. Truesdale that graduate nurses in the wards are far from satisfactory.

**Miss Harriet A. Hartry**, Minneapolis: The majority of the criticisms of superintendents of nurses are largely overdrawn. One is the question of orderliness in the hospital. The essayist missed the mark altogether when he said that the training-school superintendent insisted on the shades being straight even though a patient suffering from some unmentionable eye disease would suffer because the shade was not drawn down. That is not the meaning at all. No superintendent of nurses would object to a shade being drawn down, but what she objects to is lack of orderliness.

**Dr. Kate Lindsay**, Boulder, Colo.: I have been a practicing physician in a sanatorium. I see that the sanatorium nurse is not represented here to-day. While all honor is due to the hospital nurse, in the sanatorium, and especially in a tuberculosis sanatorium, a sanatorium for nervous diseases or a general medical and surgical sanatorium, you will find that if you appoint most of the nurses to treat a case by such physiologic medical treatment as massage, proper bathing, physiologic therapeutics, the use of electricity, dieting, and general management of the patient, she will find herself wanting; at least, that has been my experience. We all have our ideals. We cannot have our standards and our ideals too high.

So far as the nurse's health is concerned I believe that we need to give more instruction to the nurse as to how she can best conserve her own health. Efficiency is the ability to do work and yet not wear one's self out doing it by ordinary methods of work.

**Dr. Cleveland H. Shutt**, St. Louis: Most of us can tell the nurses what their ideals should be. The community owes something to the nursing profession in showing what it expects to hold out for the nurse after she has completed her training and education to become a nurse.

There is a movement on foot by one of the great independent foundations to investigate the various places from which nurses are graduated in the United States; I will not say trained, because there are many places where nurses are not trained, they simply work. I believe that there will be greater benefit derived by the nursing profession directly, and by the hospitals of the entire country indirectly, from this than from any other movement than has been inaugurated. We have, I dare say, in this country more training-schools for nurses which do not train nurses than there are training-schools that do train them. There are many institutions that specialize, doing only surgical work or only some special sort of work, who give at the end of a certain time a certificate "Trained Nurse." If certain reasonable standards are established and if the facilities which institutions offer for training of the nurse are investigated, tabulated and published, we shall get the right kind of women to apply for training. They will be eager to do so. No one should be more deeply interested in the question of standardizing training-schools for nurses than the nurses themselves. Their own organizations should take that work up because it is, I believe, the most practical movement toward the elevation of the nursing profession and toward giving the women who enter the profession what they deserve in return for their efforts and time spent in training.

**Miss Delia O'Connell**, Minneapolis: I have sometimes wondered if the scarcity of nurses in our well-equipped training-schools is not due to the fact that these schools insist on three years of unrequited training. I know that there are many women with high-school educations anxious to take up nursing who cannot afford the three years of training without salary. They can learn stenography in six months; they can take up bookkeeping, or they can enter a training-school for two years and three months, after which plenty of work as private nurses is available. They take no second-rate positions. They are good nurses.

**Dr. H. B. Howard**, Boston: There is one thing that I would like to say: Any training-school will succeed and find its place in the community as long as it is careful in selecting pupils with good dispositions and kindly manners and trains them so that these good points are cultivated and improved. The training-schools do for the nursing profession more, in some respects, than the medical schools do for the physicians that they graduate and throw on our community: they test out as to their physical ability, their ability to endure the work and to maintain an even manner under trying circumstances; in fact, their dispositions are thoroughly tried out. Those that have a bad disposition rarely pass. If a nurse has a diploma or certificate from even our poorest schools, as a rule, you will find she is a woman with a good disposition. I think that there has not been sufficient emphasis placed on this point, and I think that this is the reason why even the poorer schools do seem to fill the bill.

**Dr. John A. Hornsby**, Chicago: I am more convinced than ever that we are talking at cross-purposes with exactly the same intention. Dr. Beard is perhaps talking about a class of nurses who shall lead and teach in the profession of trained nurses; some of the rest of us are thinking about nurses to take care of patients, at home and in the hospital.

All our training-schools nowadays admit pupils only after they are 21 or 22 years old. Most young women finish their school training at 18; then they either stay at home and take their little fling in society, or learn stenography, or dressmaking, or go into a shop. When the young woman is 22 years old, she decides to become a nurse.

Now I wonder if we cannot compromise with Dr. Beard by taking the girl of 18 when she comes out of school, while her mind is still fresh and flexible and while she still has the habit of application to her books. Why cannot we take her and give her this preliminary course in school without introducing her into the wards of the hospital at all, say for six months or even a year, and then put her in the hospital and give her two years' training?

**Dr. Richard O. Beard**, Minneapolis: It is not women with university training that we seek; it is simply women with a good average degree of preliminary attainment. Nor are we going to take them at 18 years of age. We have put the age down to 20, and sometimes have been sorry that we have. It is a question of a person fresh from the study of the schools; it is a question of a person with sufficient maturity to know her own mind and to be willing to devote herself seriously to a serious vocation.

We know that it is extremely difficult to put graduate nurses and pupil-nurses together in the same institution; but we have had to do it and we are going to keep on doing it until we can get our school built up to the point at which the pupils of that school can fitly take care of the university hospitals.

I cannot for one moment share any sympathy with the principle that the system of training nurses should, under any circumstances whatsoever, be exploited for the benefit of the hospital or the hospital service. As a matter of fact, there is no inadequacy of supply of private nurses of any kind in most of our communities.

# ARTERIOVENOUS ANEURYSM OF THE SUPERFICIAL FEMORAL VESSELS *

A. B. EISENBREY, M.D.
Resident Pathologist, St. Luke's Hospital
NEW YORK

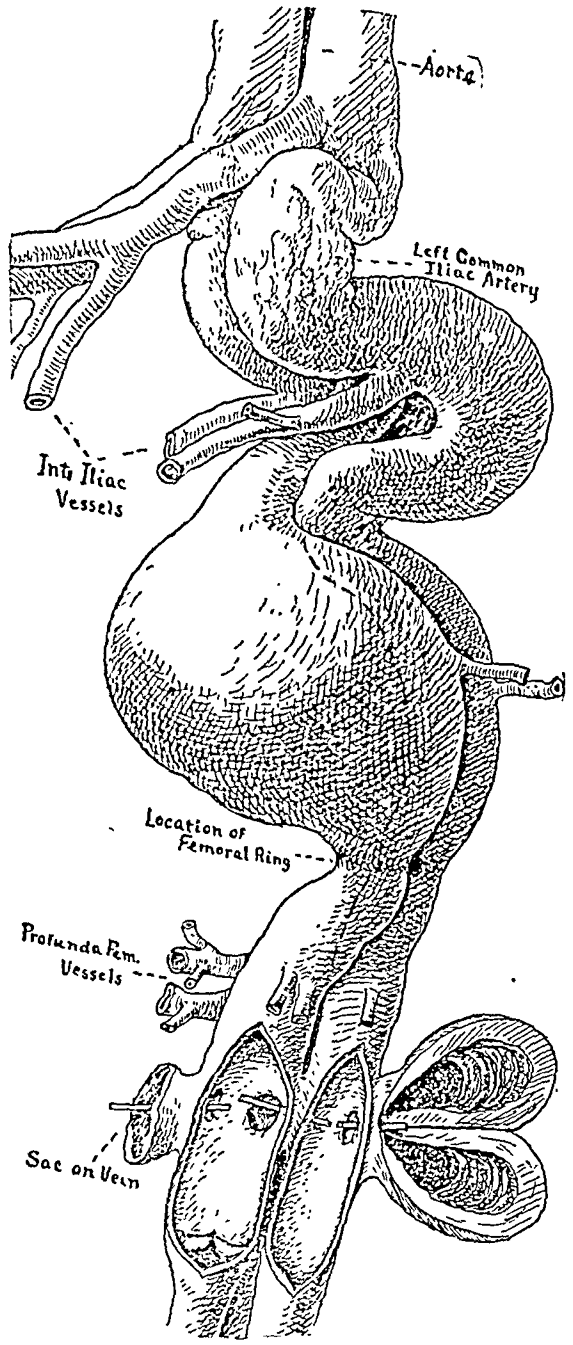
The specimen pictured herewith is of interest because of the extensive nature of the alterations in both artery and vein up to the bifurcation of the aorta and vena cava, and because of the probable bearing of these lesions on the cardiac condition, on account of which the patient entered the hospital. It is of interest also to note that, in spite of the marked nature of the lesions in the femoral and iliac vessels, no history of symptoms directly referable to them was obtained.

*History.*—The patient, a physician, aged 63, was admitted to St. Luke's Hospital, Dec. 22, 1912, on the service of Dr. Austin W. Hollis, through whose courtesy I am able to report the clinical history of the case. He complained of shortness of breath and presented symptoms of cardiac insufficiency. There was a history of some dyspnea on exertion, extending over a period of two years, while for the previous two months he had been incapacitated by marked shortness of breath even while lying down and had had some edema of the abdomen, legs and feet. He gave no history of symptoms referable to the genito-urinary, respiratory or gastro-intestinal tracts. His family history was negative. During childhood, the patient had had scarlet fever, and later in life malaria. Luetic infection was denied.

*Examination.*—This showed a cardiac dulness extending 15 cm. to the left of the sternum, murmurs referable to a mitral insufficiency and an irregular, arrhythmic pulse, averaging 90 to 100 per minute. There was moderate edema of the lower extremities and trunk. The urine was negative, except for a faint trace of albumin in one of several specimens examined. There were numerous moist râles in the lungs and signs of fluid at the right base. Relating to the condition in the left thigh, it was noted that in the left groin was a pulsating, expansile tumor, the size of a hen's egg, situated over the profunda femoral artery. Over this tumor was heard a continuous murmur which possessed a systolic accentuation. The information was obtained that about eighteen years before the patient had been shot through the thigh by a small caliber (probably 0.22) rifle bullet. The amount of disability at the time of injury was not stated, but it was known that since that time the patient had lived in and had traveled extensively through South America and had spent much time on horseback.

---

* From the Pathological Department of St. Luke's Hospital, Dr. F. C. Wood, Director.



Arteriovenous aneurysm of the superficial femoral vessels.

The meagerness of the details concerning the subsequent course of this lesion makes difficult an explanation of the extensive changes in the *external and common* iliac artery on that side. The changes in the corresponding veins, however, are explainable on purely mechanical grounds. Obviously, from the rather strenuous nature of the patient's subsequent career, he could not have been greatly incapacitated.

The patient's illness terminated fatally one week after admission.

*Necropsy.*—A general congestion of all the organs was found. The heart was dilated and hypertrophied. The right ventricular wall measured 0.6 cm. and the left wall 2.2 cm. in thickness. The muscle was pale and flabby. The right auricle was thickened and greatly dilated. The tricuspid orifice was markedly dilated, admitting five fingers readily. The mitral orifice admitted three fingers. The valves in both cases were slightly thickened, but not distorted, and showed no vegetations. The pulmonary valve was normal. The aortic orifice was dilated, the leaflets were considerably sclerosed and atheromatous change at their points of attachment was marked. No vegetations, ulcerations or distortions were present. The arch of the aorta was uniformly dilated and showed areas of rather advanced atheromatous change without ulceration, but around the orifices of the coronary arteries calcareous plaques were found. The coronary arteries were thickened and a moderate degree of atheroma was present. The aorta, from arch to bifurcation, showed irregular areas of early atheromatous change. The right common iliac presented a relatively normal appearance, while on the left side the artery had undergone most pronounced changes.

When the pelvic region was examined, the bladder, sigmoid and upper portion of the rectum were found lifted well out of the pelvis and toward the right side. This was due principally to the immense dilatation of the left external iliac vein and to the dilatation and tortuosity of the corresponding artery. Since the lesion was evidently due in large measure to a retrograde process, it is convenient to begin the description of the specimen at the site of the original injury.

The bullet had perforated the superficial femoral artery and vein where they lie in contact about 6.5 cm. distal to the point at which the profunda femoral vessels are given off. It had gone completely through each vessel, and the points of entrance and exit were situated diametrically opposite each other. The adjoining orifices in artery and vein had become closely and densely adherent to each other, and a smooth-surfaced opening of irregularly rounded outline about 0.7 cm. in diameter persisted. The perforation in the left wall of the artery presented a similar appearance and communicated with an egg-shaped, thick-walled, saccular aneurysm about 4.5 by 4 cm. in its diameters. The sac wall was firmly adherent to the surrounding muscle and fascia. Near the orifice the sac was thin and calcareous, and the cavity contained a recent clot, while the other two-thirds was filled by a dense organized clot.

In removing the specimen, owing to the collapsed condition of the vein, a portion was inadvertently left behind, for leading off from the margin of the perforation of the internal side of the vein and continuous with the wall of the vein was a margin of what was evidently the wall of a sac of a diameter considerably larger than that of the vein. Whether this was a saccular aneurysm of the vein corresponding to the one in the artery can only be conjectured. The opening was 0.6 cm. in diameter, irregular in outline and covered by intima. The inner surface of the margin of the sac wall was likewise smooth. For a distance of 1.5 cm. distal to the point of communication, the artery was dilated and the wall markedly sclerosed and atheromatous; below this point it appeared normal. The vein wall was thickened and dilated for a distance of 3 cm. below the communication, where a pair of well-developed valves was found. Below these valves the vein appeared normal. Above the communication both artery and vein were dilated to about 2.5 cm. in diameter. The arterial wall was sclerosed and atheromatous and contained calcareous plaques. The vein wall was considerably thickened. Both artery and vein diminished in size where the vessels passed beneath Poupart's ligament, assuming an oval outline with diameters of about 2 by 1.5 cm. They both immediately dilated again to their former size and the external and common iliac divisions of the artery maintained a diameter of about 2.5 to 2.8 cm. for the remainder of its course, which was in the form of a double ox-bow and increased the actual length of the vessel to 38 cm., while 15 cm. are given as the average normal length. The wall of the artery showed marked thickening, atheroma and calcification. Except for general sclerosis and marked atheromatous change about its mouth the internal iliac artery appeared normal. About 1 cm. above the femoral opening the vein dilated suddenly to form a fusiform, rather thin-walled sac, 6.5 cm. in diameter by about 7 cm. in length. In a modified degree the vein followed the tortuosity of the artery and the dilatation and thickening of the wall extended into the inferior vena cava, while the right common iliac vein appeared normal.

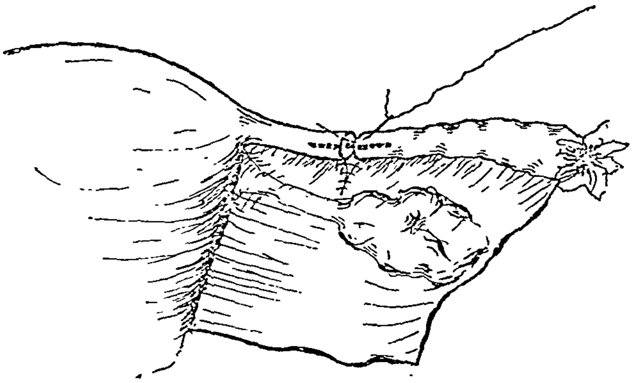
From the condition of the vena cava, its dilatation and thickening, it is reasonable to suppose that the pressure within it had been increased over a long period of time and the findings in the heart, especially on the right side, may well have been due to the distal arteriovenous communication. With a pelvis so crowded by the enormously dilated vessels it is indeed surprising that the patient gave no history of disturbances of urination or defecation. That the pressure had exerted some effect was evidenced by the fact that both ureters were dilated to about twice their normal size, and that the renal pelves were moderately dilated. Some interference with the lymphatic drainage of the left leg had occurred, for the thigh was edematous and the lymphatics and lymph-nodes in the left groin were considerably enlarged.

St. Luke's Hospital.

# A NEW METHOD OF ANASTOMOSING THE OVARIAN TUBE OR VAS DEFERENS

S. L. CHRISTIAN, M.D. and E. L. SANDERSON, M.D.
Visiting Surgeons to Charity Hospital and Schumpert Memorial Sanitarium
SHREVEPORT, LA.

Attempts at repair of the ovarian tube and vas deferens have always been fraught with uncertainty as to whether the lumen of the tube, after simple suturing, would remain patulous or would become obliterated at the site of the suture line. So far as we are able to find out, obliteration of the lumen at the line of sutures is the usual result.



New method of anastomosis as applied to ovarian tube.

It has seemed desirable that some simple method of repairing these structures that would give reasonably certain results be devised. The following plan we have used successfully in three cases, one of which will be cited as an example.

When the ovarian tube or vas deferens has been divided from any cause, the cut ends are picked up, a piece of No. 0 twenty-day catgut is inserted ⅜ inch into each end of the tube and the ends are brought together with two apposing catgut sutures, as shown in the illustration. The lumen cannot become obliterated at the time of healing of the divided ends because the gut is in the canal and will remain there until after repair is complete and Nature has ceased to throw out reparative tissue. The gut, being of absorbable material, is soon completely removed. Gentleness should be exercised in the introduction of the catgut so as not to traumatize the epithelial lining.

## CASE REPORT

Mrs. C. R., aged 29; married nine years, had never been pregnant. She was operated on two years previously, at which time the left tube and ovary were removed. She was operated on by us in February, 1913. At this time a small hemorrhagic cyst was removed from the right ovary with about ½ inch of the middle third of the corresponding tube, which was constricted from previous inflammation and proved, after removal, to have an obliterated lumen. The remainder of the tube was patulous. We then anastomosed the tube according to the technic described. This patient is now pregnant.

The operation will find a field of usefulness in the male and female in cases in which the lumen of these tubes has been destroyed.

# A CASE OF HODGKIN'S DISEASE TREATED WITH BENZENE

G. B. Lawson, M.D., Roanoke, Va., and E. A. Thomas, M.D.,
Wytheville, Va.

*History.*—The patient, G. P. K., white, a farmer aged 59, was admitted to the Jefferson Hospital, Roanoke, Va., in January, 1912. His past history was practically negative except for slight attacks of acute inflammatory rheumatism at the age of 36, again at 41 and again at 44. In March, 1911, he had an attack of fever, with headache and general aching pains. This was diagnosed as the grip. Three days after the onset the lymph-nodes on both sides of the neck began to swell, increasing rapidly for a few days, and shortly after this he noticed markedly enlarged epitrochlears. The swelling of the lymph-nodes increased gradually until the patient was admitted to the hospital.

*Examination.*—On admittance there was marked enlargement of the cervical lymph-nodes on both sides; the swelling on the two sides almost met in front, forming a collar. The individual lymph-nodes tended to be separate and freely movable. The epitrochlear lymph-nodes were about the size of a robin's egg. The lymph-nodes in the groin were only fairly enlarged. There was practically no enlargement of the lymph-nodes in the axilla. The blood showed 5,000,000 reds with hemoglobin of 90 per cent. The leukocytes numbered 7,000, with practically a normal differential count. The physical examination was otherwise practically negative.

*Treatment and Result.*—The patient was treated with the Roentgen ray for four weeks. Under this treatment the lymph-nodes with the exception of the epitrochlears gradually became smaller. A month after the Roentgen treatment was stopped the lymph-nodes were larger than before treatment. In the summer of 1912 the patient was again given Roentgen treatment, and the lymph-nodes again became smaller; but shortly after the treatment was stopped they enlarged again.

Examination in March, 1913, showed swollen lymph-nodes almost encircling the neck in front and extending out beyond the lower jaw at the sides. The epitrochlears were the size of a walnut; the lymph-nodes in the groin were somewhat enlarged, with some enlargement of the axillary lymph-nodes. There were a number of enlargements behind the shoulders and in the lumbar region. These appeared to be subcutaneous lymph-nodes. There was marked cough due to pressure on the bronchi by lymph-nodes. Shortly after this the patient was put on benzene (benzol) by Dr. Thomas. The dose was 5 minims three times a day at first, increased to 10 minims. This dose was continued for six weeks. Two weeks after the benzene was begun, the lymph-nodes everywhere began to diminish in size, and they continued to get smaller even after the benzene was stopped.

Examination in August, 1913, showed barely palpable lymph-nodes in the neck. The epitrochlears were smaller than a butter-bean. There was no enlargement in groin or axilla. The subcutaneous lymph-nodes on the back had entirely disappeared. The patient has worked hard as a farmer for the last few months.

# *New and Nonofficial Remedies*

The following additional articles have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Their acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on *investigation made by or* under the direction of the Council. Criticisms and corrections are asked for to aid in the revision of the matter before publication in the book "New and Nonofficial Remedies."

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that, so far as known, it complies with the rules adopted by the Council.

W. A. Puckner, Secretary.

**BACILLUS OF BORDET-GENGOU VACCINE.**—This vaccine is believed to be of service in the prevention and also in the treatment of whooping-cough.

Greeley Laboratories, Inc., New York City.

*Bordet-Gengou Bacillus Vaccine for Whooping-Cough Prophylaxis.*—This vaccine is marketed in three doses, containing respectively 200, 400 and 800 million killed Bordet-Gengou bacilli; put up in a special hypodermic unit container.

*Bordet-Gengou Bacillus Vaccine for Whooping-Cough Therapy.*—This vaccine is marketed in six doses containing from 100 to 800 million killed Bordet-Gengou bacilli; put up in a special hypodermic unit container.

***CULTURE OF BACILLUS BULGARICUS,*** *Fairchild.*—The Fairchild culture of bacillus bulgaricus is a pure culture in vials of the *Bacillus bulgaricus*, each vial containing about 7 Cc.

*Actions and Uses.*—The Fairchild culture of bacillus bulgaricus is designed for internal administration in the treatment of intestinal fermentative diseases with the design of accomplishing the acclimation of the bacilli, so as to secure their characteristic action against putrefactive fermentation. It is employed in body cavities by direct application to the affected area in putrefactive and suppurative conditions. The culture may be employed for all conditions for which the bacillus bulgaricus is desired, for both internal and external use.

*Dosage.*—The content of one vial is the usual daily dosage. The Fairchild culture of bacillus bulgaricus is supplied in boxes of six vials and in boxes of thirty vials. The vials must be kept in a cold place and are not guaranteed beyond the date stamped on the package.

Manufactured by Fairchild Bros. and Foster, New York City. No U. S. patent or trademark.

The br [illegible] by inoculation and incubation upon Cohendy [illegible] medium.

# *Therapeutics*

## INCONTINENCE OF URINE IN CHILDREN

This troublesome neurosis or nervous reflex of the bladder occurs mostly at night, and occurs in both boys and girls. More or less involuntary evacuation of the bladder at night is not considered abnormal in a babe or a young child, but when a child is over 4 years of age, at least, it must be considered more or less pathologic.

The most frequent tangible causes of this disturbance are worms, and especially pin-worms, elongated or adherent prepuce or adherent clitoris, and the general restlessness and poor sleep caused by adenoid tissue in the pharnyx interfering with breathing; less frequent causes are bladder irritation caused by an actual inflammation in the bladder, or by calculi. Of course simple or specific urethritis, vaginitis or any foreign matter in the vagina may be causes; so may diabetes mellitus, and diabetes insipidus, the peculiar nervous condition evidenced by polyuria.

If no one of the before-mentioned etiologic factors is present, one must assume that there is a congenital weakness of the sphincter muscle of the bladder, or that the urine is irritable and that there is a congenital hypersensitiveness of the bladder, so that the least distention causes its contraction. The normal desire to urinate *probably* comes as a rule from the posterior portion of the urethra slightly dilating and allowing urine to trickle into it. If this relaxation of the sphincter occurs abnormally, of course the reflex desire to urinate is abnormally frequent.

If any of the foregoing reflex causes of nocturnal enuresis are present, proper treatment will stop the wetting of the bed. If none of these tangible causes are present, then one must have recourse to various more or less successful treatments; and perhaps more valuable than medicinal treatment is a rearrangement of the general management of the child. It should be urged that the loosening of an adherent prepuce or an adherent clitoris may alone immediately cure the patient of wetting the bed.

The diet is important in the general management of such a child, and as soon as the child is of such an age that milk is not necessary for its food it is better to restrict the amount of milk, as nearly two-thirds of milk must be passed out by the urine. Of course coffee and tea should be eliminated from the diet of all children, especially of children suffering from this condition. The nearer the diet is vegetarian and cereal, the better for the patient, as vegetables keep more water in the intestines and pass more water out by the bowels and less by the urine than does a diet of more or less meat. All fluids should be restricted after 3 or 4 p. m. and the child should be awakened to urinate when the parents go to bed. Preventing the child from lying on its back and raising the foot of the bed are old methods which are pretty generally known. The object is to prevent, if possible, the urine trickling into the back part of the urethra and starting the vesical spasm.

While the child may be treated psychically, or mentally impressed with different physical treatments, and perhaps in some way frightened into keeping up a nocturnal memory picture of the necessity of waking when the desire to urinate occurs, still, the patient should never be punished, as this is rarely of any value.

Various electrical treatments have been tried, and *probably none* any more successfully than the faradic with an indifferent electrode over the spine and an active small electrode applied over the bladder, over the pubis and over the perineum, and the current made sufficiently strong to cause more or less contraction of the tissues. Theoretically this application of electricity may cause contraction and stimulation of the sphincter of the bladder, but most likely the greatest amount of good is done by the psychic effect on the child. Sometimes the galvanic or constant current, with the large electrode on the spine being the anode and the more active smaller electrode being the cathode and the current allowed to make and break, is successful.

Often the passing of sounds has seemed to be the cause of improvement. In other cases a cold perineal douche, or cold-water spongings applied to the perineum apparently cures the condition.

Medication has not been very *satisfactory, except* that when there is anemia, of course iron is indicated. Probably the most successful drug is atropin, either in the form of belladonna or atropin sulphate, and the amount given should be sufficient *to cause some physiologic* action. The dose to begin with would be 1/500 grain of atropin sulphate to a child 5 years old, administered at bedtime. This dose should be increased until some physiologic activity is evident. Strychnin in the form of the sulphate, or as nux vomica has been recommended, but it is theoretically contra-indicated as exciting the nervous activity of the spinal cord. Bromids to depress the irritability of the spinal cord may apparently be more indicated, but such administration of bromid for more than a few days is bad treatment for any child, as it interferes with the whole nutrition. Frequently ergot is a successful medication, especially when there is a tendency to polyuria or diabetes insipidus. The ability of ergot to stimulate smooth muscle fiber is well understood, and that it is more or less of a sedative to the central nervous system is believed by many clinicians. The ergot is best administered as a thoroughly active fluidextract in doses of 10, 15, 20 or more drops, depending on the age of the child, and given directly after the evening meal.

Though almost any treatment may at times be rapidly successful, it must not be forgotten that many of these cases of nocturnal enuresis end abruptly without any special treatment, and the most inveterate cases frequently have the trouble cease at puberty, owing probably to a better development of all the muscular tissues of the genito-urinary tract.

## IMPORTED MEDICATION

There has long been a tendency in the United States on the part of writers of scientific articles to quote largely from the work of foreign investigators, giving them due credit, and to forget to quote and give credit for as good or even better work done in this country. Our loyalty to ourselves should counteract this tendency. Many an article, valuable and well written, has a long list of quotations from workers abroad though often a very small list of references to those at home. In fact, it almost seems at times as though the work done by our own men was deliberately overlooked.

Except in case of some specific treatment, or some scientific findings, or some recent pharmacologic investigations, the imported medicinal recommendations, especially the prescriptions given for use in certain diseases or conditions, are generally worthless from the standpoint of scientific medication. Unfortunately, and probably thoughtlessly, many of the best medical journals give weight to these importations of fool prescriptions by quoting them as abstracts or in their therapeutic departments. A number of times we have called attention to this error in judgment, as it appears to us.

A large number of these questionable prescriptions come from France, and often carry with them the weight of the opinion of a noted clinician. But generally the mixtures thus offered are irrational, nauseating, many times footless, and often the principal ingredient in the prescription is a simple and well-known drug.

The two following prescriptions[1] have recently been copied from a Paris publication into one of our best journals:

A FORMULA FOR COMBINED STOMACHIC AND LAXATIVE EFFECTS

"℞

| | | | |
|---|---|---|---|
| Fluidextracti rhamni purshianae, | | ʒ v | (20 grammes) |
| Tincturae nucis vomicae, | | ʒ ss | (2 grammes) |
| Aquae laurocerasi, | | | |
| Syrupi, | āā | ℥ ss | (15 grammes) |
| Aquae destillatae, | | ℥ iii | (100 grammes) |

"M. Sig.: Three or four teaspoonfuls daily."

Cherry laurel water seems to be used in prescriptions in Germany and France much as an invocation to the gods would be—we put this cherry laurel water in, therefore the prescription will do good—much as a dash of iodoform on a fresh wound was some time since used to insure perfect asepsis.

This is the age in which patients do not desire, and often will not take, nauseating preparations. To increase the disagreeableness of the fluidextract of cascara sagrada by adding more bitter, the tincture of nux vomica, and a sickish sweet, the syrup, in a preparation to increase a patient's appetite (namely, a stomachic) is of course absurd.

If such a patient were given one or two drops of the tincture of nux vomica in a wineglass of water three times daily, before or with the meals, the appetizing effect of the bitter would be insured in the pleasantest possible way.

The laxative, cascara sagrada, could be given more pleasantly once, at bedtime or after supper, in a tablet containing an active preparation of this drug; such active tablets can be procured. This is not to discuss or to decry the practice of giving small doses of cascara sagrada two or three times a day as a laxative treatment, if the physician deems it advisable, but if that is the treatment that he desires he certainly should not make the nauseating combination above presented.

The second prescription is for the relief of amenorrhea, "in which rheumatic disturbance of the uterus is believed responsible":

"℞

| | | | |
|---|---|---|---|
| Potassii iodidi, | | ʒ ii | (8 grammes) |
| Vini colchici seminis | | ʒ i | (4 grammes) |
| Syrupi sarsaparillae compositi | | | |
| Aquae destillatae | āā q. s. ad | ℥ iss | (50 grammes) |

"M. Sig.: Three teaspoonfuls a day."

It is so delightfully simple to be able to decide that an amenorrhea is due to a rheumatic disturbance of the uterus, and it would hardly be considered fair to ask the diagnostician if he could prove it.

Certainly, the patient with a rheumatic uterus who is suffering from the pangs (?) of amenorrhea would also suffer from disturbance of the stomach if she took the mixture offered.

Iodin in any form may so stimulate the thyroid gland that it in turn will stimulate the ovaries and uterus to normal activities. But in giving potassium iodid, for instance, it seems hardly necessary to offer this ancient combination which was presented long before anyone now on earth was born (though it is not necessary to determine its exact age), when iodid was administered in the dear old syrup of sarsaparilla comp. with the addition of colchicum in some form when rheumatism or gout was supposed to be present.

It should be remembered that this prescription represents the administration of potassium iodid, wine of colchicum seeds, sarsaparilla, glycyrrhiza, glycerin, ammonia water (fluidextract of glycyrrhiza), fluidextract of senna, sugar, oil of sassafras, oil of anise, and oil of wintergreen. The Pharmacopeia says that the compound syrup of sarsaparilla and the fluidextract of glycyrrhiza may be made with ordinary water, while the prescription very carefully calls for distilled water. This questioning of the character of the water would seem needless if it were not generally absurd. The specification in a prescription of distilled water (which is often not fresh), while the other ingredients of the prescription are made with ordinary water, seems an uncalled-for refinement.

## METABOLISM IN CANCER

The study of cancer has been approached from a number of directions, which, for the most part, have been determined by the previous experience of the persons engaged in cancer research. Pathologists have been responsible for the search for infective organisms; biologists have elaborated the investigation of specific types of cell proliferation in connection with neoplasms: physiologic chemists have sought for evidences of fundamental alterations in tissue metabolism. This competition among different lines of scientific endeavor has been wholesome and stimulating to the study of disease, as it has furnished various points of view which would probably never have become recognized had it not been for the highly practical considerations which called forth so much effort on the part of many workers.

Although the investigation of the metabolism of cancer patients has contributed a large and growing literature, in the main it has remained a collection of disconnected facts and observations, some of them interesting in themselves, yet bearing no obvious relation to one another or to any underlying organic disturbance which could not be explained quite apart from the specific disease in question. Thus the protein metabolism is generally found to be exaggerated, and evidences of acidosis and an attendant increased ammonia excretion have frequently been reported. This, however, is little else than the metabolic story of partial inanition which attends the cachectic states that accompany so many chronic diseases. The "demineralization," that is, the gradual undue loss of inorganic elements from the organism, is likewise certainly not to be regarded as characteristic of cancer alone. Considerable has been written from time to time regarding the increased output of products of incomplete metabolism or oxidation in the body. Friedrich Müller and others have long since pointed out that the increased protein decomposition may be so pronounced in cases of advanced carcinoma that it is impossible to maintain the patients in nitrogenous equilibrium despite large food intakes. Some of the European investigators have laid much stress on an apparent increase in the output of so-called "oxyproteic acids" and of unoxidized or "neutral" sulphur compounds in the urine. Here again the fact that the largest figures have been found in carcinoma must be correlated with the consideration that in this disease decreased ingestion of food and intensive disintegration of tissues may go hand in hand. At any rate, without being committed to the view that the findings are pathognomonic of cancer, we may appreciate that an increased urinary elimination of incompletely catabolized protein residues — the *Eiweissschlacken* of the German authors — is present in cancer as it may be in cachexias of other sorts.

Dr. Saxl of the First Medical University Clinic in Vienna has lately attempted to interpret the diverse features of cancer metabolism from some common etiologic point of view.[1] He has called attention to the fact that many of the phenomena of metabolism which we have just reviewed are symptomatic of inadequate tissue oxidation as it is presented in the classic forms of poisoning with cyanid. Can it be that small amounts of cyanid radicals are formed in carcinoma? Hydrocyanic acid is known to arise in the metabolism of plant forms. In the animal organism, in which it is notably poisonous, it is in part detoxicated by becoming transformed into sulphocyanid. Sulphocyanids are not unknown in the secretions and excretions of the human organism.

In attempting to reconcile clinical facts with chemical theory, Saxl has actually observed that the administration of small doses of sulphocyanids leads to unmistakable excretion of the oxyproteic acid residues to which reference has already been made. Here, then, is a parallelism between the protein metabolism of the carcinomatous individual and the metabolic disturbances set up by sulphocyanids. The next step obviously was to search for sulphocyanid in the output of cancer patients. According to Saxl, the content of sulphocyanid in the urine of the latter is undeniably larger than what is found in the kidney output of healthy man or in other types of disease. The increase in sulphocyanid appears to be independent of food intake, anemia or cachexia; and such augmented elimination as may attend some febrile conditions is far smaller than that found in cancer. From these facts he draws the conclusion that there is a disturbance in sulphocyanid metabolism in carcinoma.

We have survived too many hypotheses in regard to this elusive disease to accept every new generalization, however plausible it may appear at first inspection of the evidence; yet we are always glad to recognize every scintilla of new suggestion which may furnish a welcome guide to progress. For the present we must agree with von Fürth that the discovery of a specific urinary test of diagnostic usefulness in carcinoma still remains in the land of blessed hopes.

## THE LIVER AND KETONURIA

The attempt to find the organs and tissues of the body in which definite physiologic and pathologic processes have their seat is characteristic of the modern study of intermediary metabolism. We are no longer content to ascribe some particular phenomenon to "disturbed nutrition" or "perverted metabolism"; but physiologic science seeks to ascertain and indicate with precision the nature of the upset in question and to find the special part of the organism directly concerned therewith. To some degree this has been successfully accomplished in various instances by the method of exclusion. When, for example, the thyroid or the pancreas is removed from its normal connections with the remainder of the body, the altered functions of the latter betray something of the rôle which each of these organs may be conceived to play in the normal physiologic work of the individual. Again, the method of perfusion of isolated organs has enabled the investigator to compare the intake and output of these individual anatomic parts independently of the simultaneous activity of other organs, and to draw conclusions regarding the degree and sort of participation which they are engaged in under ordinary circumstances. It is, of course, always desirable to control and corroborate the findings of such methods by suitable observations on the intact individual, wherever this is possible.

Largely as a result of perfusion studies it has been taught that the liver is the organ in which the formation of the "acetone bodies"—acetone, diacetic acid, beta-hydroxybutyric acid—goes on. What has hitherto been believed as the outcome of such indirect evidence has now been clinched by more direct experiments. Fischler and Kossow[1] have accomplished the demonstration of the correctness of the current view of excluding the participation of the liver in metabolic activities in large measure by means of the familiar expedient of an Eck fistula whereby the portal blood-supply is diverted directly into the vena cava. Animals thus prepared exhibit far less ketonuria under suitable chemical provocation than do the subjects with normal livers. On the other hand, when by a sort of reversed Eck fistula specially devised by the German investigators in the medical clinic at Heidelberg an exceptionally large blood-supply is furnished to the liver, the output of the characteristic members of the ketone group of compounds is markedly increased. The ketonuria may thereby reach enormous proportions.

Although no one is justified at present in concluding that the liver is the sole organ concerned in the phenomena of ketonuria, the sharp parallelism between the quantities of eliminated ketone derivatives and the varying degree of hepatic participation so far as it can be controlled by altering the richness of the blood-supply to the liver, furnishes the best evidence yet offered.

Fleischintoxikation beim Eck'schen Fistelhunde, Deutsch. Arch. f. klin. Med., 1913, cxi, 479.

## HUMAN PANCREATIC SECRETION

Through the inspiration of Pawlow and very largely under his personal leadership new points of view have progressively developed as to the mode in which the digestive secretions are elaborated. Derived almost entirely from experimentation on animals, the facts have nevertheless received wide application to the conditions that obtain in man. We need only mention the now familiar phenomenon of the psychic secretion of gastric juice, the possibility of stimulating and inhibiting secretion by food factors, and the influence of the latter on the enzyme content of the various alimentary digestive fluids, to indicate some of the novelties which have been introduced into the modern physiology of alimentation.

It requires no extended argument to convince one that such facts and conclusions as are the result of observations on the higher animals deserve to be verified or at least tested in every feasible way on man. Human gastric juice is not unknown in the biochemical laboratory nor has the pancreatic juice of man been an extreme rarity there. Until very recent years, however, these and similar secretions have been studied, when possible, almost solely as specimens in which acidity or alkalinity and various characteristic enzymes were demonstrated. Under the dominance of the newer ideas which involve functional adaptations as well as the mere constituents of composition, revision and renewed investigation have become imperative whenever suitable cases are found and the none too frequent opportunities arise. The pancreatic secretion obtained through a fistula in man carefully examined in the medical clinic of the University of Helsingfors by Holsti[1] has fortified our knowledge as to its function and has served to "check up" the conclusions derived from the facts of animal experimentation. First of all, it has been demonstrated for the first time, we believe, that a so-called psychic secretion of pancreatic juice occurs in man, as has also been verified for the gastric juice,[2] though the psychic factor plays a much less prominent part in the case of the pancreas. The mere sight of food or the act of mastication or swallowing is not sufficient, as it is in the case of the stomach, to induce psychic secretion of pancreatic juice. Inasmuch as the latent period prior to the actual flow of the pancreatic secretion is only one or two minutes, whereas that of the gastric juice is four or five minutes, the pancreatic flow cannot be due to an escape of "psychic" gastric juice into the duodenum, which, it is well known, will provoke a flow of pancreatic secretion. The psychic secretion of the pancreas presumably independent of gastric causes lasts about one-half hour. The continuance or cessation of further secretion depends on the nature of the ingested food. If the discharge from the stomach into the duodenum proceeds, a suitable stimulus for pancreatic flow is thereby furnished. The rate of flow is therefore modified in accord with the influence of different foodstuffs on the secretion into and the rate of discharge from the stomach. With a preponderance of carbohydrates it is prompt and long continued in contrast with the delay and brief effect evoked by pure fats. Thus comparable quantities of widely different foods furnished secretory data of the following order: rice, 51 c.c.; meat, 34 c.c.; oil, 22 c.c. The content of digestive enzymes in the secretion obtained varies widely.

The secretagogue effect of hydrochloric acid on the pancreatic function is familiar. Water is not without a distinct though evanescent action. Soda inhibits the secretion, as is the case in animals. These and other facts which need not be recited here indicate clearly that in their general features the phenomena of pancreatic secretion are essentially alike in man and the dog—the animal which has furnished the classic data on the subject.

---

### NEW TESTS FOR LIVER FUNCTION

On previous occasions we have pointed out the shortcomings of various so-called tests for functional disorders, in particular as they apply to the liver.[1] The fact that few of them measure up to the strict requirement of the specific application intended for them and that most of the proposed methods—usually in the form of tests for the comparative tolerance of sugars—involve physiologic consequences of still undemonstrated character, has placed a limitation to the wide-spread introduction of these diagnostic aids. When the liver, or any other organ, is charged with the responsibility for a certain physiologic duty, and a corresponding task is set to ascertain whether or not the organism is capable of performing it, we must be convinced, on the one hand, that the organ under examination really is *normally the effective agent* in the transformations involved, and, on the other, that no different tissue can act in a compensatory manner. Only under such carefully controlled circumstances will the failure to accomplish the task be convincing evidence of the temporary functional inefficiency of the organ involved and furnish a dependable diagnostic test.

The very fact that so few of the proposed tests for hepatic function have been able to withstand the criticisms aimed at them, and thus to become a part of diagnostic routine, makes it the more urgent to devise new ones based on carefully investigated premises. Because they appear to be supported alike by sound physiologic considerations, verified by clinical evidence, exploration and necropsy findings we refer to three new tests proposed by Whipple[2] and his collaborators at the Johns Hopkins Hospital. The first of these is the lipase test. This enzyme is present in the blood-plasma or serum of normal individuals in quite constant amount. Experimental injury of the liver, by chloroform, phosphorus or hydrazin poisoning, for instance, will always cause a rise in plasma lipase. The test appears to be of value in certain groups of human cases. In eclampsia, for example, in which liver injury is postulated by many and hemorrhagic portal liver necroses are commonly observed at necropsy, the lipase figures are high; in pernicious vomiting of pregnancy and uremia with convulsions the lipase data are normal, by way of contrast. The Baltimore investigators note that pneumonia, peritonitis, leukemias and various infections may show a rise in lipase to double the normal or even more. This need not confuse one, however, for they remark that probably in such conditions the excess of lipase is referable to liver changes, either liver injury or liver stimulation due to cell-cleavage products circulating in the blood. The lipase test can be carried out with uncomplicated apparatus and by a relatively simple technic.

A second possibility which may develop into a test for hepatic function concerns the fibrinogen normally present in blood-plasma. It has been shown that this blood protein may fluctuate with liver injury, falling to a low content at the time of the hepatic damage and returning above normal during the repair which rapidly follows.[3] From data already available it appears that when the fibrinogen is pronouncedly decreased it indicates a grave condition and may mean advanced liver injury, acute or chronic. The fibrinogen index is sometimes very low in certain cases of hepatic cirrhosis, and thus assumes the gravest prognostic import. In human cases of fatal late chloroform poisoning the fibrinogen content may likewise drop. On the assumption here involved that the liver is intimately concerned with the production of the fibrinogen, which is in turn responsible for the clotting of the blood, it is interesting to note that when the liver is exposed to minor injuries it may respond with an overproduction of fibrinogen. The small damage may be looked on, we are reminded, as a stimulus; and the high fibrinogen content found in pneumonia, septicemia, peritonitis, etc., can be explained by the action of certain substances on the liver epithelium. They may be derived from the disintegration of body-cells or foreign cells, and when very abundant may be able to cause degeneration and even liver-cell necrosis; in lesser amounts they may be imagined to have a stimulating action on the liver.

A third proposed hepatic test makes use of the drug phenoltetrachlorphthalein which has been demonstrated to be excreted by the liver into the bile.[4] This substance, which gives brilliant color responses like the other phthaleins in familiar use, must be introduced in a nonoral manner so that a determination of its appearance in the feces will serve as an index of the extent to which it is poured into the duodenum in the bile. Purgation is employed to furnish the intestinal contents promptly when desired. Studies on animals have indicated a remarkable degree of secretory activity and specificity of the liver epithelium. When liver injury is produced by chloroform, phosphorus or similar hepatic poisons the output in the feces may drop to mere traces, depending on the extent of the hepatic damage. The phthalein then comes out in the urine. The drug is not secreted by the intestinal mucosa and in complete obstructive jaundice there is never a trace of phthalein in the feces. Whipple accordingly believes that this new drug gives promise as a functional liver test. It is excreted in the bile through activity of the hepatic epithelium, not that of the bile-duct. Any agent which injures the liver parenchyma or interferes with its functional activity will cause a drop in the phthalein output in the feces.

[4] Abel, J. J., and Rountree, L.: Jour. Pharmacol. and Exper. Therap., 1909, i, 231.

Only a wide application and unbiased tests in varied conditions of disease will finally determine the clinical value of the interesting reactions here reviewed. To say the least, they promise to furnish experience which will lead to a more accurate definition and discrimination of the anatomic and functional abnormalities of the liver; for they are based on investigated physiologic considerations.

## *Current Comment*

### OZONE TO HIDE ODORS

"We have long been of the opinion," says the San Francisco *Argonaut*, "that whatever is unpleasant is bad for us, and we have endeavored in our humble and unscientific way to rule our lives accordingly. That is why we object to cold mutton and to being contradicted. They are bad for us — we felt it was so without knowing the reason." This was apropos of the contention of Dr. Hill of London that ozone is of value, not because it kills germs, but because it removes odors and the like that are injurious because they are unpleasant. Here we have an apparent conflict between esthetics and health. The instinctive shrinking from bad odors is almost a natural protective mechanism. At first thought there comes to mind only one really edible substance possessed of a bad odor, and it has fallen into some disrepute. The man who first remarked, "I smell a rat," voiced a grave suspicion. We have always been suspicious of that which was openly unpleasant, but remembering the man who "had an ax to grind," we have been more suspicious of that sweetness which masks a hidden unpleasantness. When we see a costly, intricate, whirring apparatus and perceive a new peculiar odor, our olfactory organs stimulate our association tracts, and behold, we too, begin to smell a rat!

### TRUE RECREATION

We hear much of the need of relaxation for the "tired business man" and the "jaded society woman." Their needs are supposed to be met, in the first place, by amusements devised for inert and vacant minds, and, in the last resort, by the "rest-cure." Meanwhile, as a recent writer[1] observes, our octogenarian colleague whose name is so frequently associated with this therapeutic measure is demonstrating in his own person the fact that one may fill well-ordered days with steady accomplishment and find recreation, not in passivity, but in a complete change of mental occupation. Thirty years ago Dr. S. Weir Mitchell undertook to write a novel as a vacation pastime after his winter practice. The result was "In War Time," which had a large and immediate success. The effect on Dr. Mitchell himself, even before the success of his novel came to corroborate it, was a thorough recreation, a veritable refreshment of faculties that sent him back to his work reinvigorated and satisfied. He has continued since to take up some serious literary labor every summer. His vigor of mind and body now, when well past four score years of age, attest the healthfulness of this practice begun in middle life. It is possible, indeed, that rather too exclusive stress is laid on it in the article mentioned. Doubtless Dr. Mitchell's health and long life are due in large measure to his habit of changing his environment as well as his occupation every summer. At all events, his example is instructive. *It is well to remember that many patients whose nervous condition is on the down grade toward nervous exhaustion need, not rest or frivolous amusement, but a new and absorbing mental occupation that will take their minds entirely out of the beaten tracks of their previous interests.*

### THE CRISIS IN GERMANY

According to our German exchanges, a struggle between the medical profession and the sickness-insurance societies — *Krankenkassen* — is impending, which, in the view of the medical authorities, is a life-and-death contest involving the independence of the medical profession. With remarkable unanimity, the delegates to a special meeting of the Aerztetag, the organization which deals with the economic interests of the profession, representing 23,000 physicians, decided to break off all negotiations with the insurance societies and deal hereafter only with the sick policy-holders individually. Jan. 1, 1914, there go into effect the new provisions of the insurance law extending its benefits to the great bulk of the population. The insurance societies are making strenuous efforts to secure physicians who will devote their whole time to the care of the insured and act as "strike-breakers." It is said that salaries as high as $3,750 (15,000 marks) per annum have been offered for this service. On the other hand, the organized medical men hope to hold their ranks unbroken so as to cripple the insurance societies and prevent their carrying out their contracts. There are mutual charges and recriminations. The medical men claim to have documentary evidence that the representatives of the insurance societies were only pretending to seek a basis of agreement in their negotiations, while they were really bent on defeating the demands of the physicians for the right of the insured to a free choice of their medical attendant. Medical men look on the move as an attempt to reduce them to the rank of paid employees on a starvation wage, thus taking away the freedom and dignity of the profession. The low fees may be appreciated by reading the proposed articles of agreement with the

---

[1] Versatility and Dr. S. Weir Mitchell, Century Magazine, December, 1913.

Berlin Krankenkassen as given in our Berlin letter of Oct. 25, 1913, p. 1550, where we learn that the society proposes to pay an annual sum of $1.25 per capita, while the physicians want at least $1.37.

### "MAKING FACES" AS AN AID TO HEALTH

Massage and exercise, at various times, have been advocated as a panacea for many and divers ills. Fernet[1] now proposes the idea that by exercise we may be able to influence favorably the encroaching deafness of the elderly, or that following otitis media. He remarks that children can often move the ears and part of the scalp voluntarily, and some may become quite exceptional in this faculty. Fernet believes that, through exercise, adults will be able to produce such movements. He has devised three series of exercises, as follows: The first consists of grimaces of the face, contracting in turn the muscles of the lips, nostrils and eyelids, aiming ultimately to reach the ear; next the frontal and occipital muscles are contracted alternately and then the muscles above and behind and in front of the ear. The muscles of the eustachian tube are then exercised by directions which he gives fully. He says, "Medical men, knowing the anatomy of the parts, can train their muscles very effectually in this way; others need an instructor to show them." Just what the ultimate outcome of this proposal will be is questionable. We may picture to ourselves tentatively a future period when all around us will be visible a series of grimacing, ear-wiggling elderly men and women in the act of improving their ears and warding off the encroaching deafness of old age. "Physicians, particularly," says Fernet, "need good hearing, and rather than accepting deafness with the fatalism of the Oriental, they should rise up and fight it." If it is to be combated by this method, the word "fight" is a very appropriate one.

## Medical News

### ARKANSAS

**Hospital News.**—The cornerstone of the Leon N. Levy Memorial Hospital, Hot Springs, was laid with formal ceremonies by the Little Rock Lodge B' Nai B Rith. The building is to cost when completed $100,000, and will be ready for the dedicatory ceremonies early in March.

**Personal.**—Dr. John B. Dooley has taken charge of the Little Rock City Hospital.——A formal dinner in honor of Drs. Verne R. Stover and Cory Wassell was given by the local chapter of the Chi Zeta Chi Medical Fraternity, Little Rock, recently. Dr. Stover sails in a few days for China as a medical missionary.——Dr. Ida Joe Brooks, Little Rock, has been appointed a member of the city Homeopathic Medical Board, vice Dr. William E. Green, deceased.

**New Officers.**—Pulaski County Medical Society at Little Rock, December 1: president, Dr. Alexander E. Harris; secretary, Dr. William T. McCurry.——Arkansas Society of St. Louis, Iron Mountain and Southern Railway Company surgeons at Little Rock: president, Dr. Charles S. Holt, Fort Smith; secretary-treasurer, W. F. Smith, Little Rock.——Third District Medical Society at Cotton Plant: president, Dr. Roscoe T. Gephart, Cotton Plant; secretary, Dr. Edward De W. McKnight, Brinkley.

**Railway Surgeons Elect.**—The Society of the Missouri and North Arkansas Railway Surgeons met at Heber Springs for organization, November 24, Dr. T. B. Bradford, Cotton Plant, acting as temporary chairman. Heber Springs was decided on as the place for the annual meeting to be held December 22, and the following officers were elected: president, Dr. W B. Snipes, Aubrey; vice-presidents, Drs. B. Cooper, Everton, and J. A. Henley, St. Joe; secretary, Dr. Cyrus F. Crosby, Heber Springs.

### DISTRICT OF COLUMBIA

**New Officers.**—Washington Obstetrical and Gynecological Society: president, Dr. John F. Moran; secretary, Dr. Truman Abbe.

**Schmidt on Dyspepsia.**—Prof. Adolph Schmidt was the guest of honor of the District of Columbia Medical Society, November 12, and delivered an address before the society on "Acid Dyspepsia." Prior to the meeting Dr. Schmidt was given a dinner by Dr. William Gerry Morgan.

**Women's Clinic Instituted.**—An outpatient maternity service has been inaugurated in connection with the Women's Clinic Auxiliary. This service is for the benefit of that class of society which does not wish to accept charity and yet cannot afford to pay high fees. In charge of the service are Drs. Amelia Frances Foye, Alice W. Downey, Isabel H. Lamb, Cora Smith King, Louise Ross and Lillian R. Lekites; assistant physicians are Drs. Lenora C. Volkman, Evelyn Mitchell, E. Alberta Reed and Sarah M. Siewers.

**Personal.**—The commissioner of pensions has appointed the following three medical boards of pension examiners for the district: first board, Drs. James A. Gannon, John Van Rensselaer, J. Lawn Thompson and Robert M. Ellyson, ad interim; second board, Drs. Joseph R. Biggs, Michael J. Ready, S. Clifford Cox and Lewis A. Walker, ad interim, and third board, Drs. Taylor B. Dixon, Aloysius W. Valentine, Howard Fisher and Charles H. Bowker, ad interim.——Drs. Randolph B. Carmichael and Harry C. Yarrow have been added to the consulting staff of the free night dispensary of Emergency Hospital, Washington.

### FLORIDA

**New Officers.**—Hillsboro County Medical Society at Tampa, December 2: president, Dr. John C. Knight, Plant City; secretary, Dr. Gilbert H. Hodgson, Tampa.——Pinella County Medical Society, organized at St. Petersburg: president, Dr. Lucian B. Dickerson, Clear Water; secretary-treasurer, Dr. William McC. Davis, St. Petersburg.

**Personal.**—The following staff of local physicians has been appointed for the Duval County Hospital, Jacksonville: medical, Dr. Robert H. McGinniss; surgery, Drs. Paul C. Perry and John E. Boyd; gynecology, Dr. Gerry R. Holden; neurology, Dr. James H. Randolph; laryngology, Dr. William S. Manning; andrology, Dr. Thomas C. Thompson; dermatology, Dr. Joseph Lee Kirby-Smith; pathology and bacteriology, Dr. Henry Hanson. Dr. Paul C. Perry has been elected chairman and Dr. James H. Randolph, secretary of the medical board.

### ILLINOIS

**Inebriates Barred from State Hospital.**—The superintendent of the Watertown State Hospital announces that, as the asylum is now crowded with insane patients, inebriates and other patients not insane will not be admitted to the hospital in the future.

**Personal.**—Dr. James H. Lacey, Albion, has moved to Denver, Colo., on account of his health. He has been succeeded at Albion by Dr. Ross L. Moter, formerly of Browns. His practice has been taken by Dr. Parmenter of Bellmont.——Drs. Carl E. Black, Elmer L. Crouch and George H. Stacy have moved their offices to the Ayres Bank Building, Jacksonville.

### Chicago

**Chicago Dispensary Closed.**—The Northwest Side Free Dispensary was closed November 28, and the funds of the organization were turned over to the Federated Orthodox Jewish Charities of Chicago.

**Personal.**—Dr. Charles F. Sanborn, assistant superintendent of Cook County Hospital, has been appointed superintendent of the new Cincinnati General Hospital.——Dr. Herman A. Moje was seriously injured in a collision between automobiles, December 6.——Dr. Karl H. von Klein is reported to be critically ill in Cook County Hospital.

**Vision Conservation.**—The Illinois Association for the Conservation of Vision and Prevention of Blindness accepted an invitation extended by the Illuminating Engineering Society to attend a demonstration of "Five Years' Progress in Indirect Illumination," December 10. One department of the work of the association is closely connected with the matters of illumination, eye fatigue, etc.

---

[1] Fernet: Bull. de l'Acad. de Méd., 1913, lxxvii, p. 209.

**Civil Service Examination.**—The Cook County civil service committee announces competitive examinations open to citizens of the United States for appointment on the staff of the Cook County Hospital in the following departments:

| Department of: | Date of Examination | Hour |
|---|---|---|
| Nervous and Mental Diseases | December 15 | 7 P. M. |
| Contagious Diseases | December 16 | 7 P. M. |
| Children's Diseases | December 17 | 7 P. M. |
| Tuberculosis | December 18 | 7 P. M. |
| Skin and Venereal | December 19 | 7 P. M. |
| Eye | December 22 | 7 P. M. |
| Pathology | December 23 | 7 P. M. |

Appointments are for a period of six years (no salary) with a continuous service of six hours per week throughout the year. Applications for these examinations will be forwarded on request made to Thomas B. Garland, chief examiner, Cook County Civil Service Commission, Chicago.

## MASSACHUSETTS

**Personal.**—Dr. John Wallace, Roxbury, Boston, has returned from Europe.——Dr. Alexander C. Eastman has been elected president and medical director, Dr. Oscar W. Roberts a vice-president, and Dr. Lawrence D. Chapman, a director of the Springfield Babies' Feeding Association.

**Community Sanitation.**—Eight towns with Wellesley Hills as a center are now guarded from infectious diseases by bacteriologic stations having a main station at Wellesley Hills. The towns are Belmont, Framingham, Wellesley, Needham, Weston, Melrose, Canton and Winchester. This idea of community sanitation was originated by Prof. Earl B. Phelps of the Massachusetts Institute of Technology, sanitary engineer of the Board of Health. Each town contributes from its budget a certain sum toward the maintenance of the cooperative health service and if there is a deficit, it is made up by the institute.

## MINNESOTA

**Fire in Railroad Hospital.**—Fire in the Northern Pacific Hospital, Brainerd, November 26, caused $5,000 damage, and necessitated the removal of patients from the medical ward of the institution. No casualties occurred.

**Tuberculosis Removal Law Enforced.**—The health commissioner of Minneapolis on November 20 made first use of the state law which authorizes health officers to remove tuberculosis patients from private homes to public hospitals in order to prevent the spread of infection.

**Personal.**—Dr. Arthur W. Ide, Brainerd, has been appointed division surgeon for the Northern Pacific Railroad.——Dr. Charles N. Hensel, St. Paul, fractured his right forearm while cranking his automobile, November 24.——Dr. Thomas Lowe, Pipestone, was elected president of the Southwestern Minnesota Medical Society at its annual meeting held in Worthington, November 13.

**Hospital News.**—The formal opening of the West Side General Hospital, St. Paul, took place November 27. The institution is to be operated by the Evangelical Hospital and Deaconess Home Association, which has purchased the old German Hospital and about two acres of land adjoining. About $8,000 has been expended for interior furnishing and decorations and it is planned to raise a fund of $100,000 for maintenance and improvement.

**Southern Minnesota Physicians Hold Meeting.**—The Southern Minnesota Medical Association held its annual meeting in Mankato, December 3. Dr. Robert H. Babcock, Chicago, gave an address on "Infections of the Heart," followed by a clinic, and it was voted to hold the midsummer meeting in Winona in August next. The following officers were elected: president, Dr. Hugh F. McGaughey, Winona; vice-presidents, Drs. John H. Adair, Owatonna, and Clifford C. Leck, Austin; secretary, William T. Adams, Elgin (reelected), and treasurer, Dr. George F. Merritt, St. Peter (reelected).

## MONTANA

**Personal.**—Dr. Joseph A. Tremblay, Butte, has been reappointed physician of Silverbow County.——In the case of Dr. C. V. Norcross, Butte, against Peter Scherr, in which suit was brought for $1,302 for professional services, the jury returned a verdict in favor of the plaintiff, November 26.

**Hospital Reopened.**—The Samaritan Hospital, Glendive, which was closed in September last, was reopened November 19, under the auspices of local physicians, and will hereafter be known as the Glendive General Hospital. At a meeting of the physicians interested in the new hospital, November 17, the following officers were elected: president, Dr. R. H. Beech; vice-president, Dr. Baldwin F. Consler, and secretary-treasurer, Dr. M. G. Danskin.

**Warning.**—Dr. Gaylord Warstell, Big Sandy, warns against a Mr. E. S. Armstrong, a well-fed, well-groomed, round-eyed man, about 5 feet 7 inches in height, weighing 180 pounds and apparently about 35 years of age, with quilted cloth hat and gray suit. He claims to be a representative of a Minneapolis tailoring house and makes an offer of a reduction for cash for clothing, taking the physician's check in payment. Dr. Warstell asks that anyone knowing Armstrong's home address or present whereabouts will send this, with such other information as he may possess, to him.

## NEW JERSEY

**Sterilization Law Void.**—The supreme court, at Trenton, November 18, set aside as unconstitutional the act of 1911, providing for the sterilization of epileptics, feeble-minded, criminals and other defectives.

**Personal.**—Dr. Mortimer J. Lampson, superintendent of the Jersey City Hospital, has resigned.——Dr. William D. Mingham, Newark, has been appointed a member of the consulting staff of the Essex County Hospital, Overbrook.

**Children's Colony to Be Established at Burlington.**—The proposal to establish a Burlington County colony for the care of defective children was assured at a meeting of the colony committee, when financial report showed that more than half of the $8,000 needed for the erection of buildings had been raised by private subscriptions. The work will be under the direction of the state authorities and the faculty of the Vineland School for Feeble-Minded Children have been asked to cooperate in its management.

## NEW MEXICO

**New County Society.**—At the last meeting of the State Medical Association, held in Albuquerque, the McKinley County Medical Society was granted a charter.

**Personal.**—Dr. Leroy S. Peters has purchased a part interest in the Albuquerque Sanatorium and will be associated with Dr. Abraham G. Shortle in the work of that institution.——Dr. and Mrs. Frank E. Condert, Gallup, have moved to Tempe.

**Charges against Physicians Dismissed.**—The indictments against twenty-five physicians of Albuquerque for failing to file death certificates with the county clerk at Bernalillo County were dismissed November 19, on motion of the district attorney.

## NEW YORK

**Personal.**—Dr. M. J. McGrath, Oswego, has been appointed district surgeon for the New York Central System, vice Drs. James E. Mansfield and David D. O'Brien, resigned.——Dr. Leslie M. Wilkens, Lackawanna, was seriously injured in a collision between his motor-car and a street-car in Buffalo, November 27.

**To Study Medical Laws.**—The American Association of Medical Jurisprudence was incorporated on December 5 by the secretary of state. The object of the association is the investigation and advancement of the science of medical jurisprudence. The study will be conducted principally in the State of New York and the United States of America. The directors are Reynold Webb Wilcox, Alfred E. Ommen, Charles P. Barney, John C. West and Oscar W. Ehrhorn.

### New York City

**Godlee Honored.**—Sir Rickman J. Godlee, president of the Royal College of Surgeons, was made an honorary member of the National Institute of Social Sciences, December 3, and presented with a gold medal in recognition of his services to humanity.

**Healthful Year for New York.**—The Bureau of Records announces that the city has had a most healthful year, the death-rate for the first eleven months of the year being 13.77 per 1,000 population, as against 14.08 for the corresponding period of 1912. For the week ended November 29, the death-rate was 12.51 per 1,000 population, as against 12.62 for 1912.

**New York County Medical Society Elects.**—At the one hundred and eighth annual meeting of the Medical Society of the County of New York, the following officers were elected for the following year: president, Dr. T. Passmore Berens; vice-presidents, Dr. Howard Lilienthal and Dr. Frederick E. Sondern; secretary, Dr. John Van Doren Young; assistant secretary, Dr. J. Milton Mabbott, and treasurer, Dr. Charles H. Richardson.

**Another Building for Montefiore Home.**—This institution, which has just moved into its new buildings, which were built at a cost of $2,000,000 and which accommodate 630 patients, is now planning to provide another building for the accommodation of persons able to pay wholly or in part for their treatment, and $200,000 has already been subscribed for this purpose. Until this building is completed all patients are cared for free of charge.

**Site for Mothers' Home.**—Mrs. Rudolph A. Muller has donated two acres of land as a site for the Home for Expectant Mothers, of which Mrs. Robert H. Sayre is president. She will also donate all the milk, fruit and vegetables required for the home from her own estate. The raising of funds for the buildings has already been begun. Each patient will have her own room during her month's stay in the home, and after leaving it will be under the care of the Prenatal Feeding Association, which will establish a chain of restaurants where mothers may get their lunches or will send visiting nurses to the homes to see that the mothers get proper food there.

**Needs of Hospitals.**—In the report of the Hospital Saturday and Sunday Association emphasis is laid on the increasing cost of hospital maintenance and on the decreased receipts from patients. During the past year it cost $4,932,309 to run the forty-seven hospitals of the association, an increase of $382,441 over the previous year. The income of the forty-seven hospitals last year was $18,706 less in payments from patients, $25,657 less from the city, and $21,890 less from endowment. In spite of this decrease the hospitals gave 134,272 days of hospital service, making a total of 2,084,442 days' treatment, of which 1,291,442, or 62 per cent., were entirely free.

**Laryngological Society Celebrates Anniversary.**—On November 25 the New York Laryngological Society, said to be the oldest society in the world devoted exclusively to that specialty, which was merged in 1885 with the Laryngological Section of the New York Academy of Medicine, celebrated its fortieth anniversary. Dr. William W. Carter, chairman of the section, presided. The historical address was delivered by Dr. Clinton Wagner. Dr. D. Bryson Delavan delivered a commemorative address and presented a bronze tablet and several historical memorabilia, and Dr. Carter accepted the tablet on behalf of the society. At the conclusion of the formal exercises, several short addresses were made by various members of the society and guests.

## NORTH CAROLINA

**Sanatorium Opened.**—The Wilmington Red Cross Society has completed a sanatorium about two miles from the city for the treatment of tuberculosis. The institution contains accommodations for twenty patients and provides for colored as well as white patients.

**Hospital News.**—The Good Hope Hospital was opened in Duke recently. Thanksgiving Day was made special donation day for the institution, which received benefactions from more than two hundred citizens of the town and vicinity.——A stock company with a subscribed capital of $30,000 has been organized at Elizabeth City to build a general hospital. Four of the seven directors are physicians of the city.

**Mental Hygiene Conference.**—The State Conference on Mental Hygiene was held at Raleigh, November 28 to December 2, under the direction of Dr. Albert Anderson, superintendent of the State Hospital for the Insane. As a result of this conference the North Carolina Society for Mental Hygiene Study was organized at Raleigh with a provisional executive committee composed of Dr. John McCampbell, superintendent of the Morgantown State Hospital, William W. Faison, superintendent of the Goldsboro, and Dr. Albert Anderson, superintendent of the Raleigh State Hospital. Dr. Anderson is secretary of the committee.

## OHIO

**Society Adopts Memorial Resolution.**—Summit County Medical Society at its meeting, November 4, adopted resolutions of sympathy and regret regarding the death of Dr. Herman Christian Theiss, Akron.

**Hospital News.**—The Barberton Hospital has been purchased by A. A. Besaw from Mr. and Mrs. S. A. Carpenter who had operated the institution since 1910. During the existence of the hospital, 630 patients have been treated with thirty-five deaths.

**Hospital Staff Members Banqueted.**—In celebration of the twenty-seventh anniversary of the connection of Drs. George B. Evans and Charles H. Humphreys with St. Elizabeth's Hospital, Dayton, they were given a complimentary dinner by the sisters and doctors of the staff, November 24. Dr. Henry S. Jewett, president of the staff, officiated as toastmaster.

**Hospital News.**—It is announced that sufficient funds have been collected to warrant the construction of a new Jewish hospital at Cleveland in the spring. It is planned to have an institution of 100 beds, to cost about $100,000.——St. Vincent's Charity Hospital, Cleveland, is having a week's campaign to raise $250,000 for the construction of a new wing for the institution.

**Personal.**—A. J. Ranney, for twelve years superintendent of Lakeside Hospital, Cleveland, has resigned on account of ill-health and has been succeeded by Dr. Andrew R. Warner.——Major Vernon Roberts, National Military Home, Dayton, has been appointed chief surgeon at the Milwaukee Soldiers' Home, vice Dr. Oscar Chrysler, deceased.——Drs. William T. Corlett, Henry J. Gerstenberger, Norman W. Ingalls, David Marine, and Vernon C. Rowland have returned from abroad.

**New Officers.**—Summit County Medical Society at Akron, December 2: president, Dr. David H. Morgan; secretary, Dr. Alexander S. McCormick, both of Akron.——Allen County Medical Society at Lima, November 18: president, Dr. Oliver S. Steiner; secretary, Dr. Paul Steuber, both of Lima.——Ashland County Medical Society, fifty-fourth annual session at Ashland, November 18: president, Dr. Frederick V. Dotterweich; secretary-treasurer, Dr. Cortland B. Meuser, both of Ashland.

**Western Reserve Notes.**—Dr. Oscar T. Schultz, assistant professor of pathology, has been appointed professor of pathology at the University of Nebraska.——Dr. A. A. Johnson, formerly pathologist of the City Hospital, has been appointed instructor of pathology at the University of Nebraska.——The department of pathology has moved its teaching quarters from the medical school to the pathology building of the Lakeside Hospital, that the instruction may be given in closer conjunction with the clinic and autopsy rooms.——Dr. C. M. Winn, formerly resident pathologist at St. Thomas Hospital, Panama, C. Z., has been appointed resident pathologist at Lakeside Hospital.——Drs. Hunter Robb and George N. Stewart are spending their leave of absence in Europe.——Dr. Carl A. Hamann, dean of the school, is seriously ill with streptococcus infection of the arm.

## OKLAHOMA

**Personal.**—Dr. A. S. Riddell, Chickasha, has been appointed deputy internal revenue collector for Oklahoma.——Dr. Curtis R. Day, Oklahoma City, has been elected president, and Dr. R. H. Riley, Oklahoma City, secretary-treasurer of the Oklahoma Association for the Prevention of Tuberculosis.

## PENNSYLVANIA

**Personal.**—Dr. James A. Peeples, Peters Creek, fell in his barnyard, November 29, fracturing his right leg.——Dr. Edward F. Menger, Fort Lauden, has been appointed resident physician of the Carlisle Indian School.——Dr. Edward B. Shellenberger, Warren, has been appointed assistant medical director of the state dispensary by State Commissioner of Health Dr. Samuel G. Dixon.

**Appointments in the Medical Department, University of Pittsburgh.**—The following new appointments to the faculty have been made: Dr. W. E. Gardner, assistant demonstrator in anatomy; Dr. J. W. McMeans, assistant in clinical pathology and demonstrator in pathology; Dr. J. C. Irwin, instructor in obstetrics; Dr. R. J. Cary, demonstrator in medicine; Dr. Arthur Miltenberger and John Howard Seiple, assistant demonstrators in obstetrics, and Mr. Orville J. Walker, assistant in physiology and pharmacology. The following increases in rank have likewise been provided for: Dr. Chris Gardner, from assistant demonstrator to demonstrator in anatomy; Dr. Walter L. Croll, from instructor to assistant professor in obstetrics.

**Public Drinking-Cups Prohibited.**—On December 1 the advisory board of the State Board of Health prohibited the use of the public drinking-cup and the common towel. Barbers are also forbidden to brush the eyebrows of customers with a common brush, and proprietors of public eating-houses and restaurants must thoroughly cleanse all dining-room utensils after each individual use. The school-boards, clerks of council and health officers have received copies of the new regulations. This order has resulted in the disappearance of glasses from all public drinking-fountains at the Capitol, and a combination public drinking-bowl and faucet has been installed for the use of clerks. Paper towels have also been placed in all departments. Episcopal clergymen are interested to know whether the new order will interfere with the common communion cup used in the service, as the common cup is regarded as part of the ritual.

### Philadelphia

**Personals.**—Dr. George W. Outerbridge has been selected to fill the vacancy of the visiting obstetrical staff of the Maternity Hospital of Philadelphia, caused by the resignation of Dr. Levi J. Hammond.

**Gift to the University.**—The descendants of Dr. Priestly, the discoverer of oxygen, have presented the University of Pennsylvania with a chemical balance which was used by Dr. Priestly in his experiments more than 130 years ago.

**Serum for Influenzal Meningitis.**—Physicians of Philadelphia and adjacent territory can now obtain the new serum for treating influenzal meningitis by applying to Dr. Paul A. Lewis, director of the Ayer Clinical Laboratory at the University of Pennsylvania.

**Four Jefferson Professors Honored.**—Three hundred physicians attended the reception given by Daniel Baugh in honor of four professors emeritus of Jefferson Medical College. The guests of honor were Drs. William W. Keen, William Joseph Hearn, James C. Wilson and James W. Holland.

**University Medical Societies Merged.**—The John Morgan Medical Society has been formed at the University of Pennsylvania by the consolidation of the H. C. Wood, Tyson, Ashurst and Penrose societies. The new society takes its name from the founder of the medical school.

**Volunteer Medical Staff.**—A volunteer medical staff has been formed, composed of physicians interested in the work of the West Branch of the Y. M. C. A., whose new $250,000 building at Sansom and Fifty-Second streets was opened December 1. They are Dr. Sidney E. Bateman, Dr. Paul Elmer Reiff, Dr. Gordon Saxon, Dr. Walter J. Snyder, Dr. Samuel McClary, III; Dr. Andrew F. Snively, Dr. Harrington L. Dickinson, Dr. Oscar G. Fegley and Dr. John H. Shaw.

**Little Mothers' Leagues Formed.** — December 2, Little Mothers' Leagues were formed in eleven Philadelphia schools under the auspices of the Child Federation. The establishment of these classes is only a beginning. They are not compulsory, the children being chosen by the teacher of the various schools. The teachers of the various classes are themselves instructed in the day's lesson and merely repeat it to the children. The instruction is given the teachers by Dr. Samuel McClintock Hamill.

**Medicine of Assyria and Babylonia.**—An address will be delivered by Prof. Morris Jastrow of the University of Pennsylvania on "The Medicine of the Babylonians and Assyrians," before the Section on Medical History of the College of Physicians, in Thomson Hall at the college, December 16. This will result from the noted Assyriologist's translation of the ancient tablet lately presented to the college by Drs. S. Weir Mitchell and Richard H. Harte, the Assyrian medical code being for the first time revealed.

**Advancing Joint Lecture Course.**—In order that the Rush Society may be truly representative in its activity, a revision of its constitution and by-laws in two particulars was voted at the special meeting called for that purpose. The name of the society has been lengthened to read "The Rush Society for the Correlation and Support of Medical and Biological Lectures in Philadelphia," and the distinction between active and associate members has been abolished and it is now provided that "any person interested in the objects of the society may become a member on the payment of the annual dues of $2." It is believed that by these changes the effectiveness of the lectures in Philadelphia will be increased, since while each lecture will remain autonomous, the united effort will aid all to obtain an increase in publicity, attendance and financial support.

### SOUTH CAROLINA

**Tuberculosis Clinic Has Permanent Quarters.**—The tuberculosis clinic of the Columbia Associated Charities opened November 26 in its new quarters at 917 Main Street. The clinic is open daily from 12 to 1 o'clock. Two physicians are in attendance.

**Faculty Changes.**—The trustees of the Medical College of the State of South Carolina, Charleston, at their meeting November 25, elected Dr. Charles P. Aimar, Charleston, professor of general surgery, vice Dr. Charles M. Rees, deceased; Dr. Allen J. Jervey, professor of the principles of surgery and surgical pathology, and Dr. Daniel L. McGuire, assistant professor of surgery.

**New Hospital Opened.**—The Camden Hospital was opened in Camden, December 1. The hospital was built by Bernard M. Baruch in commemoration of the beginning of the medical career in that town of his father, Dr. Simon Baruch, New York City. The hospital has an endowment of nearly $100,000, a bequest from John Burdell, and is unique as a rural hospital in that it has a dispensary attached at which incipient cases of tuberculosis may early be detected.

**New Officers.**—Greenville County Medical Society at Greenville, December 1: president, Dr. Charles O. Bates; secretary, Dr. Samuel G. Glover (reelected), both of Greenville.——Charleston County Medical Society at Charleston, November 6: president, Dr. William H. Johnson; secretary, Dr. Michael M. Edwards (reelected), both of Charleston. Arrangements for building an annex to the Hospital and Training School for Nurses were submitted, and a committee was appointed to secure donations for the furnishing of the new rooms.

### WISCONSIN

**New Officers.**—West Wisconsin District Medical Society: tenth annual meeting at Eau Claire, November 25: president, Dr. Eugene E. Tupper; secretary, Dr. Joseph C. Baird, both of Eau Claire.

**Settlement of Minahan Estate.**—In the Probate Court in Fond du Lac, November 25, final settlement was made of the estate of Dr. William E. Minahan, a victim of the *Titanic* disaster. The estate is appraised at more than $83,000.

**Protest by Medical Society.**—The Waukesha City Medical Society has passed resolutions protesting against any action by the city council which will lessen the investment of $15,000 in the hospital building. In the opinion of the society, a hospital with a capacity of less than fifteen or twenty beds cannot be made self-supporting.

**Osteopaths May Not Practice Without License.**—The Wisconsin Superior Court has handed down a decision in the case of W. A. Arnold, sheriff of Milwaukee County, versus Herbert Schmidt, setting forth that osteopaths cannot practice medicine in *Wisconsin without first obtaining a license*. The sheriff was directed to take the defendant into custody.

**Dinner to New Professors.**—The medical faculty of Marquette University, Milwaukee, gave a dinner to the new professors in the medical department at the Hotel Pfister, December 6. Drs. Albert J. Ochsner and Henry B. Favill of Chicago, Professor Bardeen of the University of Wisconsin, and the dean of the medical department of the University of Minnesota were among the speakers.

**Personal.**—Dr. William E. Scollard, Milwaukee, is reported to have been adjudged insane, November 21.——Dr. Lewis A. Kliese, Milwaukee, has been appointed examining physician for Milwaukee County of the insurance department of the state.——Dr. William F. Lorenz of the staff of the Mendota City Hospital, has been detailed by the U. S. Public Health Service to make a special study of pellagra.——Dr. James W. Frew, Milwaukee, has been commissioned Major, M.C., N. G. Wisconsin, and assigned to duty with the First Infantry.——Dr. Charles H. Lemon has been elected president of the Milwaukee branch of the American Electric Railway Association.

**County Sanatorium Notes.**—Dane, Waupaca and Winnebago counties have voted down the proposition to use county tuberculosis sanatoriums.——Lakeside Sanitarium, Oshkosh, was formally opened November 26, and on this occasion there was a joint meeting of the Waukesha City and County Medical Societies.——Sunnyrest Sanatorium, the Racine County Institution for the care and treatment of tuberculosis, was finally turned over to the county board, November 27. The building was constructed and equipped for less than $35,000.——The county board of Marinette County has appropriated $20,000 for a county tuberculosis sanatorium.——Brown County Board of Supervisors has appropriated $25,000 for a tuberculosis sanatorium.

### GENERAL

**Tri-State Physicians Hold Meeting.**—At the thirtieth annual meeting of the Tri-State Medical Association of Mississippi, Arkansas and Tennessee held in Memphis, November 11 to 13, the following officers were elected: president, Dr. John Darrington, Yazoo City, Miss.; vice-presidents, Drs. W. D. McCalip, Yazoo City, Miss.; E. C. McDaniel, Tyronza, Ark., and H. B. Everett, Binghamton, Tenn.; secretary, Dr. J. L. Andrews, Memphis (*reelected*), and treasurer, Dr. J. A. Vaughan, Memphis (reelected).

**Bacteriologists to Meet.**—The annual meeting of the Society of American Bacteriologists will be held in Montreal, Dec. 31, 1913, and Jan. 1 and 2, 1914, under the presidency of

Prof. C. E. A. Winslow. The meeting of January 1 will be held at McDowell College, the other meetings at the medical building of McGill University. The president's address on "Characterization and Classification of Bacteriologic Types" will follow the annual dinner at the University College, January 1. Dr. A. Parker Hitchens, Glen Olden, Pa., is secretary of the society.

**Anti-Alcohol and Narcotic Advocates Meet.**—The forty-third annual meeting of the American Society for the Study of Alcohol and Other Narcotics was held in Philadelphia, December 3 and 4, and the following officers were elected: president, Dr. John J. Kindred, New York City; vice-presidents, Drs. Alfred Gordon, Philadelphia; Daniel H. Kress, Loma Linda, Cal.; Thomas A. MacNicholl, New York City; Tom A. Williams, Washington, D. C., and Col. L. Mervin Maus, M. C., U. S. Army; secretary, Dr. G. A. Benton, Miami, Fla.; assistant secretary, Dr. De Lancey Carter, New York City; corresponding secretary, Dr. Thomas D. Crowthers, Hartford, Conn., and treasurer, Dr. Pitts Edwin Howes, Boston.

**Educational Effect of Medical Inspection in the Schools.**—According to the weekly *Bulletin* of the New York City Board of Health the percentage of children requiring treatment for defects other than those of the teeth has declined from 44.20 in 1909, to 30.1 in 1913. The percentage of those requiring dental treatment declined from 57 in 1909, to 49.4 in 1912; defective vision from 13.4 in 1909, to 7.3 in 1912; defective nasal breathing from 18.7 in 1909, to 7.6 in 1912; enlarged tonsils from 22 in 1909, to 10.4 in 1912; malnutrition from 3.14 in 1909, to 2.8 in 1912. By persistent follow-up work in the homes the percentage of glasses procured has increased from 27 in 1909, to 50.5 in 1912, and of tonsil operations from 22 in 1909, to 29 in 1912.

## FOREIGN

**Penalized for Alleged Violation of Professional Secrecy.**—Our exchanges state that the insurance company refused to pay the accident insurance on a workingman who had been killed in an industrial accident, basing this refusal on the fact that the physician of the hospital where the man had died (Lille, Belgium) had found at necropsy that the victim had leukemia, and had so informed the insurance company doctor when he inquired in regard to the necropsy findings. The widow brought suit against the hospital physician claiming violation of professional secrecy. The local court acquitted him but the recent decision of the court of appeals held him responsible both from the civil and the pecuniary standpoints.

## CANADA

**News Items.**—It is expected that in 1915 courses will commence in the new British Columbia University, of which institution Dr. Frank F. Wesbrook recently accepted the presidency.——Winnipeg had 192 cases of infectious diseases in October with nineteen deaths. Regina, Sask., had sixty-three cases of typhoid fever in October.——Medical inspection of factories to eliminate conditions producing "industrial diseases," will shortly occupy the attention of the Toronto health department.——The Ontario Board of Health has ordered Ottawa to provide a new and safe water-supply.

**Hospital News.**—Mr. John Ross Robertson, Toronto, has donated $10,000 for the purpose of furnishing the new wing of the Hospital for Sick Children. The city of Toronto gave $250,000 for building this new wing.——At Chatham, Ontario, December 1, Dr. John L. Bray, Toronto, registrar of the Ontario Medical Council, opened a new wing to St. Joseph's Hospital.——The Home for Incurable Children, Toronto, cared for thirty-one children during the past hospital year. Two new patients were admitted during the year, three were discharged and one died. The receipts for the year were $15.508.11.

**Personal.**—Dr. L. N. MacKechnie, port officer at Vancouver, B. C., has received instructions from the Director-General of Public Health at Ottawa, Dr. F. Montizambert, to make an inquiry into the prevalence of bubonic plague-infected rats that are now so prevalent at Seattle and Tacoma.——Dr. George A. B. Hall, medical officer of health, of Vancouver, states that city has not been so free in the last five years from infective diseases as at present.——Dr. Neil McNeil, Prince Rupert, B. C., has left for Europe.——Dr. Louis Laberge, medical officer of health of E. Montreal, has resigned after twenty-eight years' service.——Dr. Clarence L. Starr, Toronto, has been appointed chief surgeon at the Hospital for Sick Children.

## LONDON LETTER

*(From Our Regular Correspondent)*

London, Nov. 29, 1913.

### The British Medical Association and the Insurance Act

Dr. Alfred Cox, medical secretary to the British Medical Association, has delivered an address to the Glasgow and West of Scotland branch in which he foreshadowed important changes which were likely to occur in the relations between the profession and the government in the working of the National insurance act. He pointed out that the individual physician was quite able to look after his own interests when dealing with individual patients, but when it came to dealing with organized bodies he must have some association behind him, and there was none even remotely eligible for this purpose except the British Medical Association. In future the profession would have many more dealings with organized bodies than it ever had in the past, and instead of doing anything to split it up into classes and thereby weaken it, every man should do his best to strengthen the one association which could progress to speak in the name of the profession. Some of the physicians who had not gone on the panels (that is, served under the act), were saying that the association had now become a pro-panel body and was of no use to nonpanel physicians. The history of the association showed that there had never been a time when the interest of one section of the profession had not been balanced against the interests of other sections, and on the whole this had been fairly done. Consolidation of the profession was important, for there was nothing to hope for from either political party. The danger in front of the profession was that the prominent politicians in favor of a whole-time service would have their way. At the end of 1915, when the present system of medical benefit had to be reviewed, there would be a bigger fight in front of the profession than it ever had. It would have to repel assertions that the remuneration was excessive for the work done, and attempts would probably be made to reduce the remuneration, or what amounted to the same thing, increase the work. Any successful attempt to reduce the remuneration would have a reflex action on other forms of medical remuneration.

Another question which would come up would be the provision under the act of medical attendance on the dependents of insured persons. If they were included, about three-fourths of the whole population would be swept in. The panel service had the inherent defects of contract practice, but owing to the efforts of the association it included many good points of private practice as compared with the old lodge practice and was infinitely superior. The lodge doctor, if he did not keep on good terms with the small clique which ruled every lodge, was under a considerable risk of losing the whole society. This could not happen in panel practice and the remuneration was much better.

With regard to the proposed increase of the subscription to the association (from $6 to $10 a year), he asked that if it was proposed to begin *de novo* to organize the profession and provide a first-class medical journal, would they commence with a subscription of $6 a year? This subscription had been based on old conditions which had long since passed. The profession was making greater demands on the association every year. It was also proposed to create a special fund which could be used for exigencies which might arise. A great source of weakness in the struggle which had just taken place with the government was that the association had no fund except on paper out of which it could say to a physician who was hesitating whether or not he would follow the lead of the association, "If you will back up the rest of the profession we have money to devote to seeing you through any financial difficulty which may arise."

### Therapeutic Possibilities of Polonium

Sir William Ramsey, the eminent chemist, speaking at a meeting of the British Radium Corporation, which is producing radium from certain ores in Cornwall, held out the prospect that there were other substances in all radium ores which might be used therapeutically. They were polonium, ionium and actinium, which at present were chemical curiosities that had not been extracted in any great quantity, though there was no very great difficulty in extracting them. He was in hopes that polonium, which was perhaps most easily produced, might prove to have therapeutic qualities. Polonium was somewhat analogous to selenium, tellurium and also to bismuth, the therapeutic qualities of which had been tested. These three elements remained in the system for some length of time, and were then excreted, but they had practically no therapeutic qualities. Polonium differed from them entirely in that it gave off alpha-rays just as radium did, and the potency of radium for therapeutic purposes appeared to depend on the alpha-rays. Radium could not be administered as a medicine. It was too expensive and probably too dangerous, as he did not believe it would be easily eliminated from the system; but the three substances he had mentioned were eliminated in about three months, and his impression was that polonium might produce its effect for about that time and then be eliminated. Of ionium and actinium he could say less, but possibly they might replace radium for the uses for which it was at the moment employed.

### The Passing of Malaria

At a meeting of the Royal Colonial Institute, Dr. Malcolm Watson gave an account of his work in the prevention of malaria in the Federated Malay States. He showed that at any rate as regards dry cultivation, pool-breeding mosquitoes could be abolished by open drainage, that stream-breeders could not be so abolished, but required drainage, and that countries with no hill-stream breeders had no hill malaria. He described investigations which he had carried out in other parts of the world where malarious conditions more or less prevailed, in the Duars at the foot of the Himalayas, and in the Jeypore hills in Madras; in Sumatra, Panama, British Guiana and Barbadoes, and declared that the new knowledge had given absolute control over the malaria of low, flat land, and high hopes of control over that in hill-land. There was also every hope of abolishing malaria from rice-fields. He believed that the prevention of malaria, the improvement in health of the agriculturist and the cultivation of the land were all intimately connected, and that what helped the one would improve the other.

### Alfred Russel Wallace

Alfred Russel Wallace, who discovered the principle of natural selection independently of Darwin, has died in his ninety-first year. He was born at Usk in Monmouthshire and adopted the profession of land surveyor. At an early age he was attracted to natural history, in which he took a great interest. In 1847 he undertook a voyage to South America as a naturalist and sent home many communications to scientific societies during the four years. In 1854 he went on an expedition to the Malay Archipelago, where he remained for eight years. Here he laid the foundation of the principle of geographical distribution which has since been known as "Wallace's law," and he began to study the question of the origin and mutability of species. While pondering over these subjects he recalled the principles laid down many years before on the limitation of the human population by Malthus, and then the idea of natural selection came to him as by a sudden inspiration. About the same time Darwin was led to the same discovery, curiously from reading the same work. They both sent papers on the subject to the Linnean Society, each unaware of the other's work. The society decided that the two papers should be read at the same meeting, which took place July 1, 1858. To the end of his life he took a great interest in biologic subjects and was also an ardent democrat and social reformer.

### The Prevention of Glass-Workers' Cataract

Sir William Crookes, the eminent scientist, communicated to the Royal Society some experiments in which he has been engaged for six years with the object of providing protecting glasses to prevent damage to the eyes of glass-workers and others exposed to severe glare. The problem was to find a means of cutting off the heat-rays that are injurious to the eyes of glass-workers, in some cases predisposing to cataract, if not actually causing it. The experiments were conducted by mixing various metallic oxids with soda-glass. The metals used were cerium, chromium, cobalt, copper, iron, lead, manganese, neodymium, nickel, praseodymium and uranium. Each specimen of glass was cut and polished in plates 2 mm. thick. The glass was tested by the spectroscope to determine which of the light-rays were cut off, and by a specially devised instrument to find out what proportion of heat-rays was arrested. Sir William Crookes succeeded in preparing a glass that cut off the chemical, the ultraviolet and the heat-rays, but he could not avoid some light-rays being also cut off. It was not an advantage to have absolutely colorless glass, because a very bright light such as that from white cliffs, expanses of snow and electric light was known to be injurious to the eye, and therefore a tinted glass combining good obstruction to heat radiation and to ultraviolet rays was the best to aim at. He had produced glasses which cut off over 90 per cent. of heat radiation, which were opaque to the invisible ultraviolet rays, and were sufficiently free from color to be capable of use as spectacles. Several glasses of the type described were demonstrated to the society, showing how a neutral tint could be produced by making use of both cobalt and nickel. In the course of the discussion that followed attention was drawn to the influence of potassium in glass in modifying the colors caused by the admixture of nickel oxid.

## PARIS LETTER

*(From Our Regular Correspondent)*

PARIS, Nov. 28, 1913.

### Dedication of the Monument to Professor Dieulafoy

November 23 the monument in memory of Professor Dieulafoy was dedicated at the Hôtel-Dieu, and placed at the entrance of the Trousseau Amphitheater where Dr. Dieulafoy taught for many years. Dieulafoy's favorite pupil, Professor Widal, in an interesting address retraced his master's glorious career as a scientist and teacher.

### Admission of Women into Administrative Offices of the Public Charities

The *Journal officiel* publishes an important circular addressed by the minister of the interior to the prefects with regard to the employment of women in the administrative offices of the public charities. Women are going to be necessary in the administration of the laws, which are about to become effective, with regard to aid to large families and to women in childbirth. The last-named law makes the giving of aid conditional on the observance of prescribed conditions with regard to rest and hygiene. Moreover, it especially favors mothers who during the period of aid nurse their children themselves. It is undeniable that women would be much better qualified to see that these conditions have been observed as far as is compatible with the demands of domestic life. While the aid of women is particularly desirable in this connection, the minister wishes to see it extended also to hospitals, where competent and well-instructed women can give very valuable services with regard to the management of the establishment, quality of the linen, cooking and improvements in the quarters reserved for women and children and in maternity services.

### Kneading Bread by Machinery

The law subjects a baker to higher taxation if he installs a kneading machine. At the last session of the council on hygiene, the question of the taxation of bakers was taken up and a resolution was passed that bakers who used kneading machines should not be more highly taxed than those who used hand kneading. Such a tax is unjust because bakers who use machinery bring about two important improvements: In the first place, they are able to furnish their customers clean bread, free from the impurities introduced by hand kneading; and in the second place, the change is favorable to the health of the journeymen bakers, since the kneading is the most health-endangering part of the work.

### The Inventor of the Steam-Engine a Doctor of Medicine

The real inventor of the steam-engine was Denis Papin, who was born in Blois in 1647. James Watt and the others who perfected the engine only developed the ideas of Papin, who was the first to recognize the elasticity of steam. The name of *marmite de Papin* (Papin's kettle) is still applied to a thick kettle furnished with a valve which is hermetically closed by a weighted lever. When the interior pressure of the steam becomes sufficient, the valve opens. Papin first applied this principle to culinary uses. Meats were quickly and cheaply cooked by this apparatus. M. Charles Nordmann, astronomer at the Observatory of Paris, has rediscovered Papin's work, published in 1682, which bears as its subtitle: "Machine Invented by M. Papin, Doctor of Medicine." Papin was a physician and took his degree at the University of Paris.

### Celebration of the Twenty-Fifth Anniversary of the Pasteur Institute

The twenty-fifth anniversary of the Institut Pasteur was celebrated November 13. Speeches were made by the President of the Republic and other notables. Dr. Roux, director of the Pasteur Institute, in his speech, showed how the combined force of creative imagination and rigorous experimental methods permitted Pasteur to found a new branch of chemistry, to solve the question of spontaneous generation, and to illumine the mystery of fermentations and of infectious diseases. Not being a physician, Pasteur hesitated long to take up the subject of infectious diseases and perhaps never would have done so if the great chemist Dumas had not influenced him to seek for a remedy for the silkworm disease which was ruining the silk industry. Pasteur, encouraged by his success with the silkworm disease, took up the study of contagious diseases of the higher animals, and from 1880 to 1885 made a series of remarkable discoveries: the attenuation of virus, vaccination against anthrax and the preventive treatment of rabies. The application to man of the antirabic treatment aroused enthusiasm. The Académie des Sciences undertook to raise a public subscription for funds to build an institute where Pasteur could pursue his researches and apply his discoveries. Such was the origin of the Institut Pasteur, which I have mentioned in a previous letter (The Journal, Oct. 4. 1913. p. 1307).

### Presence of the Spirochaeta Pallida in the Blood of General Paralytics

Dr. C. Levaditi has undertaken the investigation of the question whether syphilitic infection in general paralytics is limited to the brain or if it is diffused through the blood and the various organs with accidental localization in the cerebral cortex. November 10 he read before the Académie des sciences the results of his researches in collaboration with Dr. Danulesco. The blood of a general paralytic at the third stage, syphilitic fifteen years, was inoculated into the scrotum of a rabbit; at the end of 127 days there was a bilateral scrotal lesion. Ultramicroscopic examination showed many characteristic mobile spirochetes. The striking feature is the persistence of the parasite in the blood long after the beginning of the syphilis—fifteen years. Levaditi and Danulesco had had only one positive result in six trials (five paralytics and one tabetic). It seems, then, that the germ does not exist constantly in the general circulation. Perhaps it appears there only intermittently during the phases which precede or accompany the cerebral manifestations.

### The Student Locum Tenens

According to the law of 1892 on practice of medicine, a medical student who has finished his course may be authorized, without having taken the examinations, to practice medicine as a locum tenens, but it is necessary to obtain an authorization from the prefect. A recent investigation has shown that many such medical students are practicing without having asked or obtained authorization from the prefects. It has also been found that practice has also been carried on by foreign students who do not fulfil the conditions required for the state diploma for doctor of medicine, which alone gives the right to practice in France, as distinguished from the doctor's diploma from the university. A circular letter has, therefore, been addressed to the prefects, requiring them to see that the law is observed.

### The Glory of Pasteur

The Académie française decided yesterday that the subject of the contest in poetry in 1915 (prize, 4,000 francs, or $800) shall be "The Glory of Pasteur."

## BERLIN LETTER

*(From Our Regular Correspondent)*

Berlin, Nov. 21, 1913.

### Personal

Professor Roemer of Marburg has been called to Greifswald to conduct the hygienic institute as the successor of Geheimrat Loeffler.

### The Struggle Between Krankenkasse and Physicians

Continued expressions of sympathy for their German colleagues are being published from medical societies, medical chambers, and medical faculties. A few days ago the Berlin medical faculty declared its solidarity with the German medical profession. According to newspaper reports, the governments of some of the federal states are endeavoring to influence the highest imperial authority, the office of the interior, to make a new attempt to bring about an agreement between the two parties. I regard this statement as improbable.

### Transfer of Destitute Insane from Great Britain

The following agreement has been reached between the German Empire and Great Britain regarding the transfer of destitute insane. Insane who belong in one country and come under the care of public charity in the other country may be transferred to their native country on demand of the foreign country, provided that since their last entrance into the foreign country not more than fourteen months have elapsed. This period is reckoned backward from the day on which the request for transfer reaches the government of the native country. The insane are to be transferred only after the native government has indicated its acceptance and designated the place of transfer.

### Coeducation

At the congress for juvenile education held at Breslau a few days ago, Professor Cohn discussed the difference of the sexes from his experience in Baden which in contrast to Prussia and other states of the empire, permits girls to attend the higher schools for boys. Cohn sent a number of questionnaires to the principals of schools with reference to their experience in coeducation, and discussed the answers which he had tabulated. Great interest attaches to the replies to the question whether erotic relations had developed between the boy and girl pupils. The answers are overwhelmingly negative. Cohn believes that this question can be treated with the greatest calmness, for the attraction of the sexes for each other will result in undesirable occurrences whether there is coeducation or not. Objectionable conduct will be quite as rare among coeducated pupils as among those not educated together; indeed it may be said that coeducation may contribute to lessen the tension between the sexes. Cohn draws the following practical conclusions from the collective investigation. Separate instruction may in itself be better in view of the different objects of interest for boys and girls, and even the vast American experience supports this view. In addition the greater readiness to fatigue in girls especially during the years of puberty, which is not noticed in boys, indicates the propriety of separate instruction. On the other hand, the objections against coeducation are not so great that it should be forbidden where it is desirable, because the small number of girl pupils does not permit the establishment of special schools for girls.

A long discussion followed the address in which a number of speakers opposed the method of coeducation. It was emphasized that these investigations were conducted on altogether too small material, and had also taken the wrong way to secure facts on which reliable scientific conclusions could be based. More extensive investigations must first be made before a complete scientific decision of this question could be reached.

### Death Rate of the German Empire in 1912

The Imperial Health Office has published the following statistics bearing on the frequency of certain important causes of death from about 400 urban communities. The number born living increased by 0.1 per cent. The increase, however, is found only among illegitimate births which amounted to 3.209, while the number of legitimate children born was 2,577 less. The number of stillbirths also increased by 100, which was wholly attributable to the illegitimate children. On the other hand, the birth rate had fallen from 256.6 per 10,000 in the previous year to 251.2. As a further unsatisfactory circumstance the number of stillbirths per 10,000 children born living amounted in the previous year to 322, but in 1912 to 324. The death-rate has fallen about 8.4 per cent., or 33,178. in contrast to 1911, which was very unfavorable in this respect. The death-rate sank from 16.32 to 14.60 per 1,000 of population. Especially the number of deaths in the first year of life was markedly reduced, compared with the previous year, by about 25.2 per cent. As a result the death-rate compared with 100 born living fell from 18.9 to 14.1.

As to the causes of death, an increase was observed in deaths from whooping-cough of 736, or 22.6 per cent.; from measles and rötheln of 160, or 4.8 per cent.; from diseases of the respiratory tract of 562, or 1.1 per cent.; from murder and manslaughter of 116, or 24.5 per cent.; from suicide of 443, or 6.9 per cent.; and as a result of accident of 390, or 4.2 per cent. On the other hand, there was a reduction in the number of deaths from gastro-intestinal catarrh and diarrhea, of 30,346, or 51.8 per cent.; from typhoid of 585, or 39.3 per cent.; from diphtheria and croup of 1,123, or 16.6 per cent.; from scarlet fever of 259, or 9.4 per cent.; from puerperal fever of 83, or 5.8 per cent., and from tuberculosis of 725, or 1.7 per cent. The number of deaths from gastro-intestinal catarrh and diarrhea in children under a year old diminished more than a half, from 49,409 in the previous year to 24,129. The excess of births over deaths rose from 9.35 in 1911, to 10.51 in the year of this report.

## VIENNA LETTER

(*From Our Regular Correspondent*)

Vienna, Nov. 12, 1913.

### The Meeting of German Natural Scientists and Medical Men

A few weeks ago Vienna was the meeting place of the eighty-fifth annual congress of the Deutsche Naturforscher und Aerzte, which lasted eight days. More than a thousand papers were on the official list in the thirty-four sections, and more than five thousand members formed the audience. The gathering outgrew its original aim, and it must be said that as in medical literature many superfluous articles are written, so here numerous papers should not have been read, being of insufficient importance.

The analogy between human and mouse cancer was dealt with in a paper by Dr. Frankl of Vienna. Von Hausemann had rejected all conclusions drawn from the observations of cancer in the mouse until proof of the identity of human and mouse cancer was forthcoming. Dr. Frankl's experiments show that there is no essential difference between the cells of the cancers in man or mouse. The difference, which is chiefly histologic and biologic, does not contrevert the knowledge gained hitherto from experimental mouse cancer in its bearing on human cancer.

The relations between cancer and infectious diseases was the subject of a paper by Schmidt of Innsbruck. He does not believe in a living virus of cancer. He has found that the rule "cancerous ancestors, tuberculous offspring," and its reverse, "tuberculous ancestors, cancerous offspring," are very frequent. He also finds that the history of cancer patients rarely shows infectious diseases: In 44 per cent. of stomach cancers the "infection index" was 0. This peculiar hyperimmunity of cancerous patients is presented also in a refractory behavior of the organism toward vaccination with cow's lymph. The explanation might be found in the supposition that the serum after infectious diseases contains a relative protecting body against cancer.

The dosage of diphtheria antitoxin was investigated by Schick, Kassowitz and Busatti. They recommend the use of 100 units of antitoxin per kilogram of body-weight, in mild cases, and 500 units per kilogram in severe cases. Repeated injections are unnecessary.

Dr. Mall read a paper on spasmophilia in children. By variations of feeding he succeeded experimentally in producing hyperirritability of nerves in animals, which finally resulted in rachitic changes. He thus could prove the correlation of these two frequent conditions of childhood, and showed also the important rôle played herein by the parathyroid.

Taussig read a paper on endemic goiter in Austria. He showed that out of each thousand recruits presented for admission to the army twenty-nine had to be dismissed for goiter. Taussig believes that water derived from mountains is goiter-producing, by lacking an unknown substance, which controls the equilibrium of the thyroid gland. Free consumption of meat seems to be a very good remedy against this trouble; a vegetarian life seems to promote the goitrous tendency.

One of the most important papers was the report on syphilis and general paralysis by Nonne, who asserts that at present the problem is not yet solved as to who will become tabetic or paralytic and who not. It is certain that both tabes and general paralysis of the insane are true syphilitic diseases. These patients are actively diseased. But it seems that there is a special genus of *Spirochaeta pallida* which has special affinity for the nervous system and produces syphilis of the meninges and the nerves. Even in very early cases one sometimes sees affections of the brain and its covers. These persons are predisposed to fall victims to general paralysis of the insane or to tabetic conditions.

Dr. Hock emphasized the necessity of conserving the first teeth of childhood in order to keep the mouth and jaws in a condition fit to receive the permanent teeth. In some cases it is advisable to remove, after the twelfth year of age, the first permanent molar tooth, which by this time has served its object. This removal gives space for the wisdom-tooth to break through without the usual trouble. Dr. Hock believes that this simple procedure does away with a large percentage of dental caries otherwise so frequent.

The problem of mixing human races with each other was discussed by Fischer, who said that although little experimental work is existing in this field, nevertheless it could be shown that mendelian laws were obeyed. Racial features were just as well inherited as parental general features, and they were often split, but not lost in the grandchildren. In a similar paper Abel showed that as yet there is no single absolute proof known for a real morphologic atavism in animals. The law may be formulated that an organ which in the course of ontology (during development of the genus) has become rudimentary never regains its original strength. Even if later on its presence should be required, it is replaced by an analogous organ.

The metabolism of iron in the body of the new-born was studied by Drs. Langstein and Edelstein (Berlin). They found that within the first week of life the infant loses iron by means of the bowels and that not until later is the metal retained and stored up from the food.

The importance of water in the metabolism of infants was shown by Dr. Lederer. He found that the human (and animal) organism is subjected to a gradual loss of water normally. Children with disturbances of the alimentary harmony show increased contents of water in the organs; also those with the exudative diathesis with their tendency to frequent catarrhs. The disturbance of water metabolism is thus one of the chief sources of disease in childhood (adenoid ring). This investigation proves the correctness of the ancient supposition of "constitution," which now has been placed on a safe chemical-physical base.

Interesting papers were read also at the meeting of the psychologists; one by Kafka of Munich, especially, aroused much discussion. This investigator studied the psychology of animals, and demands that careful attention be paid to this important part of biology, as it offers valuable clues to the understanding of human psychology as well as for general knowledge of the development of conscience. Analogy with human psychology could not be disregarded except for unscientific reasons.

The fight against malaria in Austria was described by Dr. von Celebrini of Trieste. He advised the regular intake of quinin daily during the malaria season, at least 5 grains per dose for adults. Children must be treated too, otherwise the whole campaign is useless. Mechanical protection from *Anopheles* is worthless and costly; best is the destruction of insects, practiced according to their biologic conditions in the affected districts.

Other papers were read on the use of india-rubber for covering warships; the future of our earth; the theories of the tides; the refutation of Newton's law of gravitation; modern methods of stereoscopic photography; paleontology and human development; the color-sense of animals; the tectonic structure of the Alps; the chemical substance used by Hannibal to dissolve the rocks of the Alps, etc. After the congress was over, a large number of visitors remained in Vienna and availed themselves of the opportunity of visiting the medical and scientific institutes of this city.

## *Marriages*

Francis Elsworth Hypes, M.D., Dunreith, Ind., to Miss Lynn Wiltshire of New Paris, O., at Dayton, O., November 24.

William Campbell, M.D., Corona, N. Y., to Miss Minnie Louise Murrell of Rockaway Beach, L. I., N. Y., November 26.

John Godfrey Thompson, M.D., to Miss Frances Lucile Young, both of Helena, Mont., November 26.

Joseph Edward Miller, M.D., Wayland, Mo., to Miss Lela Fern Harris of Sullivan, Ill., November 18.

William Leake Mann, Jr., M.D, U.S.N., to Miss Ann Fegan of Dallas, Tex., November 25.

John Hooe Iden, M.D., U.S.N., to Miss Marianna D. Brazil! at Portsmouth, R. I., November 22.

Ralph Crissman Brown, M.D., to Miss Marion Phoebe Mills, both of Chicago, December 2.

Orvan Charles Adkins, M.D., to Miss Ruth Emeline Miller, both of Elnora, Ind., November 21.

Frederick V. Burnham, M.D., Detroit, Mich., to Miss Nellie Berg of Boston, November 26.

James W. Thomas, M.D., to Miss Rose Murdoch, both of Nehawka, Neb., November 23.

E. J. Donohue, M.D., to Miss Elizabeth Mueller, both of Antigo, Wis., November 26.

Leo Kessel, M.D., to Miss Evelyn Goldsmith, both of New York City, November 24.

# Deaths

**John Guerrant Trevilian, M.D.** Medical College of Virginia, Richmond, 1861; *a Fellow of the American Medical Association*; surgeon in the Confederate service throughout the Civil War and at its close brigade surgeon and chief of field hospitals; chief surgeon of the Confederate Home and medical department of the city almshouse at Richmond; died at his home in that city, November 24, aged 73. The medical profession of Richmond met with the Richmond Academy of Medicine and Surgery, November 25, *to take suitable action regarding the death of Dr. Trevilian.*

**Thomas S. Crofford, M.D.** Hospital College of Medicine, Louisville, 1876; a member of the Tennessee State Medical Association, and American Association of Obstetricians and Gynecologists; pro[illegible] in Memphis Hospital Medical College; [illegible] Joseph's Hospital and obstetrician to the Memphis City Hospital; proprietor of Crofford's Sanitarium, Memphis; prominent as a surgeon of Memphis for many years; *for the last year a resident of California; died at his home* in Los Angeles, November 24, from pneumonia, aged 54.

**Henry Matt. Winans, M.D.** Medical College of Ohio, Cincinnati, 1880; a Fellow of the American Medical Association; a member of the State Board of Education; one of the founders and president of the People's Trust Company, Muncie, Ind.; prominent not only as a practitioner, but as a financier and philanthropist; died in a hospital in Muncie, November 23, *from malignant disease of the throat*, aged 58. At a special meeting of the Delaware County Medical Society, November 24, *resolutions of regret and sympathy were unanimously adopted.*

**John Howe Clark, M.D.** Medical Director and Rear Admiral, U. S. Navy (retired); Harvard Medical School, 1862; who since retirement had lived in Amherst, N. H.; a surgeon of the navy since 1861 and in 1893 appointed medical director and president of the *Navy Examining Board; died at his home in* Amherst, *December 1, from cerebral hemorrhage*, aged 76.

**Oliver D. Simmons, M.D.** Maryland Medical College, Baltimore, 1906; Atlantic Medical College, Baltimore, 1909; a member of the Medical and Chirurgical Faculty of Maryland; president of the Calvert County Board of School Commissioners and twice a member of the House of Delegates; died at his home near Bowens, November 25, aged 45.

**Robert Alvin Walker, M.D.** University of Wooster, Cleveland, 1879; of West Monterey, Pa.; a Fellow of the American Medical Association and once president of the Clarion County, Pa., Medical Society; a member of the General Assembly in 1905 and 1906; died suddenly while making a professional call in Monterey, November 26, aged 59.

**William A. B. Treadway, M.D.** University of Michigan, Ann Arbor, 1883; *a Fellow of the American Medical Association*; formerly a member of the medical staff of the Rhode Island State Hospital and the Givens Sanitarium, Stamford, Conn.; died in the Stamford Hospital, *November 18, from pneumonia*, aged 54.

**William Wright Williams, M.D.** Rush Medical College, 1871; Bellevue Hospital Medical College, 1874; said to have been the oldest practitioner of Mattoon, Ill.; died in the University Hospital, Chicago, November 20, eighteen days after an operation for the removal of the prostate gland, aged 66.

**Frederic Matthew Helbig, M.D.** Bellevue Hospital Medical College, 1890; a Fellow of the American Medical Association and a member of the New York State Board of Pharmacy; died at his home in New York City, November 26, *from peritonitis*, aged 47.

**John Decker Frazer, M.D.** University College of Medicine, Richmond, 1902; a Fellow of the American Medical Association, and a practitioner of Danton, Va.; aged 37; was dragged to death by a runaway horse in Orange County, Va., November 26.

**Marshall P. Austin, M.D.** University of Michigan Homeopathic College, Ann Arbor, 1881; formerly of *Minneapolis*, Minn., but for about ten years a resident of Medina, Mexico, died in that city, November 20, from pneumonia, aged 64.

**Gideon Mitchell Duncan, M.D.** McGill University, Montreal, 1871; once president of the Canadian Medical Association; died at his home in Bathurst, N. B., October 5, aged 71.

**Gaston Graham Bell, M.D.** University College of Medicine, Richmond, Va., 1900; died at his home in Oriental, N. C., November 22.

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

## TEXAS GUINAN

### Another Fraudulent Obesity "Cure"

Quackery is disreputable and vicious, because, as a rule, it not only defrauds but also trifles with health and life itself. Occasionally there are varieties of quackery that attack only the purse. The Texas Guinan obesity "cure" is one of these.

Texas Guinan is an actress. Her connection with the obesity cure that bears her name is explained briefly in the following news item that appeared in the papers early in August of this year:

> "DENVER, Colo., Aug. 4.—Marjorie Hamilton has been deposed as the light in the lives of fat women who seek to reduce, and a new queen reigns in her stead, the Denver stage favorite, Texas Guinan, according to a telegram received from that young woman to-day.
>
> "The message says she has been paid $50,000 by Walter C. Cunningham, Marjorie Hamilton's husband, and head of the fat reduction bureau, and H. D. Turner of Los Angeles, for the method she says she used in reducing herself from 204 pounds to 134."

Most of THE JOURNAL's readers will remember its exposure of "Marjorie Hamilton's Obesity Cure" and the individual who operated it, Walter C. Cunningham. The federal authorities followed up this exposure, and Cunningham and his wife, Marjorie, were indicted by the federal grand jury and later arrested.

#### A RETROSPECT

To recapitulate briefly: In 1906 Cunningham is said to have served a term of eight months in jail in Minneapolis for fraudulently listing fees when he was "president and manager" of a real-estate business of that city, conducted under various names. After completing his jail sentence, Cunningham, it is said, went to Rochester, N. Y., where he became associated with the Clark-Adkin-Neal syndicate, which has exploited various mail-order medical fakes. At this time he is said to have married Evelyn Burlingame and soon thereafter to have gone to Buffalo, where he started a mail-order business, selling "beauty treatments." The business was conducted in his wife's name. In 1909 Cunningham transferred his operations to Chicago, where, after a brief period of employment with the Currier Publishing Company, he started a mail-order bust-developer and wrinkle-eradicator concern under the name of his wife, Evelyn Cunningham. In 1910 Cunningham sold his interest in this concern and incorporated another one along the same lines—the Della Carson Company—later disposing of this also. In the meantime he was divorced from Evelyn, and on Sept. 19, 1911, married Marjorie Hamilton—the "Calendar Girl"—who, on Sept. 6, 1911, had obtained a divorce from her previous husband, William Kerting. Kerting, according to the newspapers, sued Cunningham for $25,000 for alienating his wife's affections. At the time of his marriage to Marjorie Hamilton, Cunningham had left Chicago and had opened a new establishment in Denver. Here he exploited the "Marjorie Hamilton Obesity Cure," the "Princess Tokio Beauty Company" and the "Cunningham Mail-Order School." THE JOURNAL's exposure of these three frauds made them unprofitable, and the next the public heard of Cunningham's activities was that given in the newspaper item reproduced above.

As late as Aug. 5, 1913, the newspapers reported that Marjorie Hamilton was about to get a divorce from Cunningham, charging that this gentleman "did everything mean, even to punching her face." Marjorie, in an interview published in a Chicago newspaper at that time, expressed herself thus:

> "Mr. Cunningham has another scheme now for money making. I'd advise the people who are dealing with him to look out. He has advertised his successes very widely, but he has kept his failures intensely quiet. He is like a balloon that would blow up in a moment if a pin should stick it."

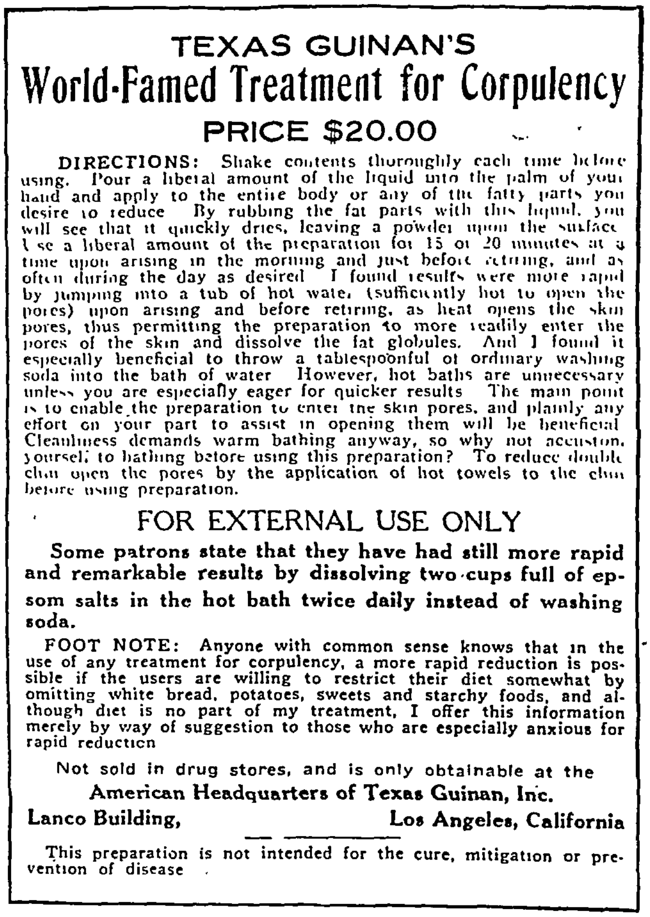
We have, then, historically considered, the following enterprises of Mr. Cunningham:

North American Land Co.: fraudulent real estate.
Evelyn Burlingame: mail-order beauty treatment.
Evelyn Cunningham: mail-order bust developer and wrinkle eradicator.
Della Carson: mail-order bust developer, wrinkle eradicator and fat reducer.
Marjorie Hamilton: mail-order fat reducer.
Princess Tokio: mail-order beauty treatment.
Texas Guinan: mail-order fat reducer.

#### TEXAS TO THE RESCUE

Texas Guinan comes to the obese public—especially the female portion of it—with this alluring challenge:

> "I have at last, finally and forever, conquered the mystery of harmlessly reducing flesh! I challenge the world to produce any person I cannot promptly take down in weight, and guarantee to make slender quickly."



TEXAS GUINAN'S

World-Famed Treatment for Corpulency

PRICE $20.00

**DIRECTIONS:** Shake contents thoroughly each time before using. Pour a liberal amount of the liquid into the palm of your hand and apply to the entire body or any of the fatty parts you desire to reduce. By rubbing the fat parts with this liquid, you will see that it quickly dries, leaving a powder upon the surface. Use a liberal amount of the preparation for 15 or 20 minutes at a time upon arising in the morning and just before retiring, and as often during the day as desired. I found results were more rapid by jumping into a tub of hot water (sufficiently hot to open the pores) upon arising and before retiring, as heat opens the skin pores, thus permitting the preparation to more readily enter the pores of the skin and dissolve the fat globules. And I found it especially beneficial to throw a tablespoonful of ordinary washing soda into the bath of water. However, hot baths are unnecessary unless you are especially eager for quicker results. The main point is to enable the preparation to enter the skin pores, and plainly any effort on your part to assist in opening them will be beneficial. Cleanliness demands warm bathing anyway, so why not accustom yourself to bathing before using this preparation? To reduce double chin open the pores by the application of hot towels to the chin before using preparation.

FOR EXTERNAL USE ONLY

**Some patrons state that they have had still more rapid and remarkable results by dissolving two cups full of epsom salts in the hot bath twice daily instead of washing soda.**

**FOOT NOTE:** Anyone with common sense knows that in the use of any treatment for corpulency, a more rapid reduction is possible if the users are willing to restrict their diet somewhat by omitting white bread, potatoes, sweets and starchy foods, and although diet is no part of my treatment, I offer this information merely by way of suggestion to those who are especially anxious for rapid reduction.

Not sold in drug stores, and is only obtainable at the

**American Headquarters of Texas Guinan, Inc.**

**Lanco Building, Los Angeles, California**

This preparation is not intended for the cure, mitigation or prevention of disease.

Fig. 1.—Photographic reproduction of the directions on the label attached to Texas Guinan's thirty cents' worth of alcohol and alum. The stuff is purchased on the understanding that no massage, dieting and exercise are necessary!

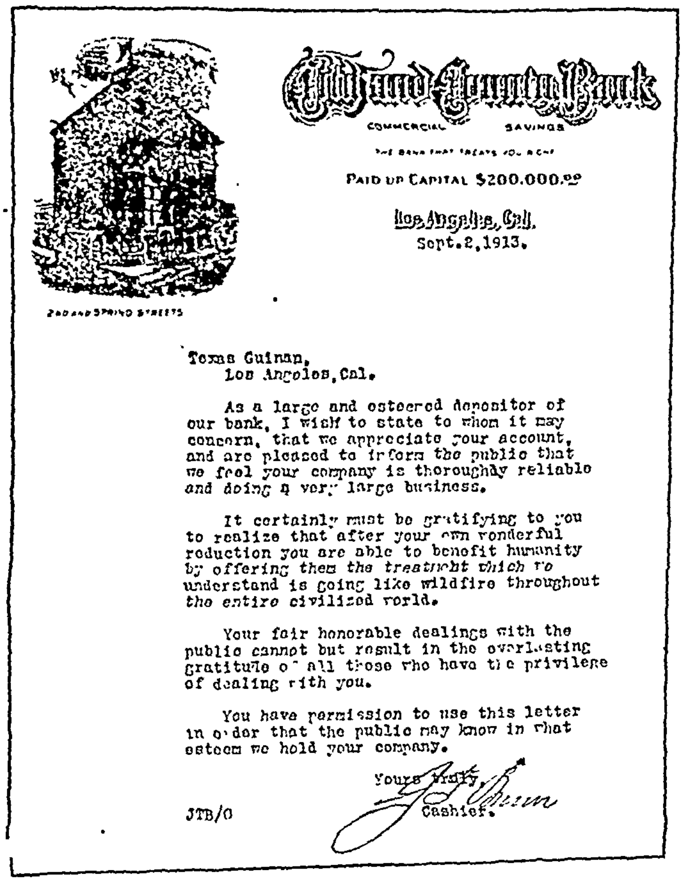
Like most obesity cures of the so-called drugless variety, the Texas Guinan humbug is "entirely different" from anything else! To quote: "It is not like the Marjorie Hamilton treatment—as absolutely different as day from night." Neither, according to Texas, is the treatment anything like the Dr. Bradford treatment, the Dr. Turner treatment, the Susanna Cocroft treatment, the Dr. Kellogg treatment, the Dr. Spillinger treatment, the Burns Belt or Hattie Beal treatment, nor like "Fat Foe," "Fat Off," "Berledets" or the Annette Kellerman treatment.

Texas says she has to laugh when she realizes how much money she squandered "trying the various fat-reducing treatments so heavily advertised by charlatans of the American Medical Association." In fact, she advises her fat sisters, "Tell the quack A. M. A. doctors and specialists to go hang."

### THE COMPLETE LETTER WRITER OF QUACKERY

It is an education in quackery to receive a complete set of the advertising matter, follow-up letters, booklets etc., sent out by Cunningham, or shall we say Texas? The booklet which those who answer the advertisements receive, is in itself a gem of impudence and mendacity. It contains various pictures of Texas Guinan in different varieties of stage dress and undress—fat, lean and medium. In it the lady tells how she was about to lose her position because she was getting too fat. "In tights I was a sight at 204 pounds," she says, and publishes a picture to prove it. Mr. Shubert, the theatrical gentleman, we are told, patted her on the shoulder "and led me quietly to the door leading out of the private entrance of his office." Thus cast into outer darkness, she determined to remove her surplus fat, and finally "out of the chaos came an inspiration."

She followed out the "inspiration" and took off 17½ pounds in ten days—we have her word for it! Joy returned! "I was found dancing before the mirror, singing as a full-throated field lark sings at dawn." Day by day, she says, she saw her "limbs that had been so big and ugly and cumbersome regain their lost slimness and beautiful lines;" she saw her "big bust . . . slowly subside back to its original shape"; her abdomen "lost its swollen and unnatural appearance"; in fact, "the days passed like happy dreams." Naturally, she went back to Mr. Shubert, who, with a due appreciation of poetic justice, at once "dictated a contract that made my eyes stick out."



City and County Bank
COMMERCIAL SAVINGS
The Bank that Treats You Right
Paid up Capital $200.000.00
2nd and Spring Streets

Los Angeles, Cal.
Sept.2,1913.

Texas Guinan,
Los Angeles, Cal.

As a large and esteemed depositor of our bank, I wish to state to whom it may concern, that we appreciate your account, and are pleased to inform the public that we feel your company is thoroughly reliable and doing a very large business.

It certainly must be gratifying to you to realize that after your own wonderful reduction you are able to benefit humanity by offering them the treatment which we understand is going like wildfire throughout the entire civilized world.

Your fair honorable dealings with the public cannot but result in the everlasting gratitude of all those who have the privilege of dealing with you.

You have permission to use this letter in order that the public may know in what esteem we hold your company.

Yours truly,
Cashier.

JTB/O

Fig. 2.—Some banks are willing agents of quackery. The City and County Bank of Los Angeles describes as "fair, honorable dealing" a business which sells, under fraudulent claims, thirty-cents' worth of simple drugs for twenty dollars.

### A REQUEST FROM A LEAN MAN

Being desirous of finding out all that could be found out about Mr. Cunningham's latest venture, the member of The Journal staff in charge of this department wrote the following letter to Texas Guinan:

> "Dear Madam: Please send me your new book that is free and oblige."

The name signed was one of several assumed in writing for quack literature; no prefix, "Miss" or "Mrs.," was put before the signature. This point is mentioned because, as will be seen later, this short, non-committal, uninforming, unemotional. strictly business-like note from a lean man was to bring a series of heart-to-heart letters from Texas Guinan. "My dear friend" wrote Texas—but let her speak for herself:

> "I am sincerely glad to get personally acquainted with you through your reply to my advertisement. I am positive it is going to prove a friendship that will result in a world of boundless happiness for you, of a deep, sincere unforgetting gratitude on your part for the great, glorious, precious new liberty that will be yours after you have been forever released from the cruel prison of Fat that has so long held you captive; when you will arise in the morning and greet each beautiful new-born day with a glad song *upon your lips instead of a sigh*; when you will glow from head to foot with a thrilling exultation of becoming slender day by day, actually seeing with your own eyes the superfluous flesh melt away; and instead of the flabby ungainly lines, the new and bewildering grace of youth will steal as if by magic over your entire form."

The "bewildering grace of youth" was an appealing promise —to a lean man of 40—and the enthusiasm of Texas was contagious.

> "Listen, dear friend: I am so wildly enthusiastic over my world-thrilling, perfect and positive fat reducer that I am madly impatient for every fat human being in the universe to get the wonderful benefits of it right away!"

"Madly impatient" is good. Why this mad impatience, may be explained by the following paragraph that occurs a little further along in the letter:

> "I am a woman, and in this thing heart and soul, out of the great joy it has brought me both to be slender and to see all others slender, so if you will fill out the enclosed guarantee order blank and send it at once, with $20.00, there will be sent you immediately under plain cover, the complete guaranteed Texas Guinan positive fat reducing treatment, of which you have never dreamed, and which the world has never before seen advertised in America."

For a paltry $20 Texas was "madly impatient" to send her unfailing treatment! *And how simple and harmless it was to prove!*

> "With this absolutely unfailing fat reducer, let me firmly impress upon you that you have no internal medicine to take, no nauseous pills, tablets, or powders, no exercise of any kind—not one, no tortuous massage, no masks or apparatus, no rollers, none of the old, moth-eaten, worn-out, silly, senseless, daily self-denial, or third degree methods. I guarantee all this, and on the day you receive the treatment you will yourself be happily aware that you have at last found the only real and rational treatment known to the world's science."

And, after dilating on the evils and tortures of fatness:

> "After the dark hours, dear friend, comes the dawn. This dawn is now for YOU!"

Then came the peroration and the letter closed:

> "Hoping to receive your $20.00 order as soon as possible, I am, Your Deeply Sincere and Sympathetic Friend, Texas Guinan."

### THE SECOND LETTER COMES

Four days after the first letter was received, Letter No. 2 arrived, in which Texas says:

> "I am puzzled! More puzzled than disappointed at failing to get a warmly enthusiastic response from you before now."

She need not have been puzzled, as she failed to allow sufficient time to elapse between the first and second letters for an answer to her first letter to reach Los Angeles from Chicago, even had it been written at the earliest possible moment. Possibly Miss Guinan expected a telegram.

> "Well knowing your inmost yearning, burning desire to be slender, and feeling sure you fully realize my positive treatment will make you so, I even expected your Rush Reply by Special Delivery."

Evidently the trouble lay in the letter sent from The Journal office. It was too confiding, too personal, for Texas says:

> "Truly, from the way you answered my advertisement, I felt positive you were Intensely in Earnest in your great longing to be rid of your fat."

Apparently, too, the once obese actress had read into the letter that was sent her, something that was certainly never intended, for we read:

> "You know there's sometimes a Wireless System of Sympathetic Understanding between human beings. Your letter, strangely enough, filled me with the almost uncontrollable desire to Rush this

Positive Reducer to you at Once; to even take it to you myself; to get on the train and go to you with it and remain with you for several days. . . ."

Evidently on thinking over the matter more carefully, Texas Guinan controlled her "almost uncontrollable desire," and instead of coming to Chicago in person, sent the letter—which was probably just as well. Yet there surely is no doubt that the lady is much in earnest.:

> "When I electrified my friends and admirers and all the theatrical world by my quick transformation from fat-girl to thin-girl: When I stunned to speechless Surprise and Satisfaction that Great Manager Mr. Shubert (whose former criticism of my over-weight had stung me to the soul)—when I Dazzled him with my fresh, new, fairy slenderness of figure, my lithe-limbed, small-waisted winsomeness from head to heal [Spelling original with Texas—Ed.]—why, dear friend, the Happy Scene it made when I presented myself before him, a New-Born, Superbly Sculptured Being and—Presto, I Stepped Across the Thrilling Threshold of 'Stardom.' Ah, my friend, no change, no scene, can e'er efface, my mind's impression of that time and place."

All of this preliminary to great "offer"; to the "one chance to save $10 on the Texas Guinan Positive Fat Reducer." For a mere $10 it was possible for the more or less cadaverous male who received this letter to get a preparation that, "from the very moment you receive it, There Is No Power on Earth That Can Keep You from Losing Flesh Rapidly . . ." The change that he would undergo would be remarkable:

> "Your chin—throat—arms—abdomen—hips—thighs and lower limbs are immediately destined for almost unbelievable alteration; your enchanting, new and graceful willowness more noticeable every blessed day . . ."

### LETTER NUMBER THREE

And with this wonderful promise, Texas closes her letter, from "Yours for New Youth and a New Deal with Destiny." With man-like perversity, even this letter remained unanswered, and as a result, Letter No. 3 came in due time, and in this Miss Guinan became even more personal:

> "Pardon me, dear, you may think me awfully conceited, but I AM a bit proud of what great critics have said in the press about me and my newly made-over form. You, too would be—for we are only women after all—and Beauty and Admiration are a part of our very lives, aren't they, dear!"

Almost uncanny are the powers of Texas:

> "But I can see you in my mind's eye today, Dear Friend, as you really are."

Here we are afraid Texas is mistaken. If she really could see her "dear friend" as he is, she would have instructed her corps of typists to remove his name from the mailing-list and charge up to profit and loss the stationery and postage already expended. Still it was hard to refrain from sending the $10, when for this small sum such a product would be sent.

> "BEHOLD! I believe I have right in my hand a treatment designed to make you Beautifully Sinuous, Fascinatingly Slender and Adorable! I believe I have right in my hand the power to give you back the Glory of Youth's Lithsome Grace, a pliant, peerless, reed-like form."

"Reedlike form" seems particularly good as applied to the recipient of this letter; the only criticism offered is that it should have applied to the present instead of the future. Nevertheless and notwithstanding the fact that Texas closed her letter "with sincere, Sisterly Solicitude," the $10 was not sent.

### THEN THE FOURTH LETTER

One might have imagined that after three such pleading epistles, Miss Guinan would feel that she was indeed casting her pearls before swine. But no, Letter No. 4 came strictly on time, with the explanation:

> "As long as you are still among the Piteous Prisoners of Fat, fat-girded, fat-manacled, fat menaced, I cannot find it in my heart to forget you! Really, truly, sincerely, dear, I cannot for the life of me, blot out of my mind, the awful unrest, the dull, desperate unhappiness you must feel!"

As has been surmised, the letter that brought this flood of correspondence from Miss Guinan was not sufficiently impersonal.

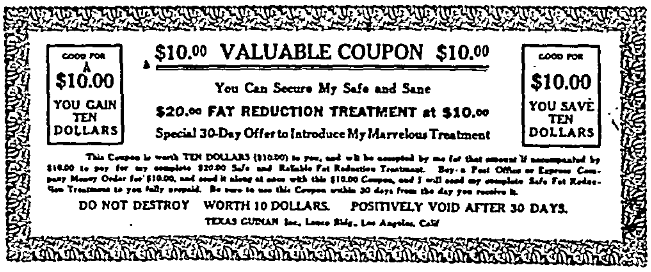
> "Your answer to my advertisement was, in itself, full of pathos to me, for I understood it through and through!"

Unlike the lady in Mr. Kipling's poem, Texas, it seems, did understand, and having understood, exhibits an "all-conquering sympathy for you that makes me forget the sordid money part of it all." She has a "great surprise" that will make it Doubly Easy and Even Profitable for you to grow slender with lightening [More original spelling.—Ed.] speed." This is it:

> "Here, my dear, I am making you a most Sisterly Proposition! I could not be more liberal if I were your own flesh and blood!"

The "sisterly proposition" is an offer of the Texas Guinan $20 "obesity cure" for the "small price of $5." All she asks is that you send in "the names and addresses of five fat men or women," which Miss Guinan considers "worth $15." This, the fourth letter, begins to exhibit a spirit of doubtfulness, as though its writer was slowly becoming convinced that the person to whom it was addressed did not think much of the Texas Guinan "obesity cure." To dispel any growing skepticism, we are told that should we stop a moment and reason we must inevitably conclude that every statement Texas Guinan has made regarding her cure "must be true, because my reputation is at stake. I am traveling the country starring in 'The Passing Show of 1912,' backed by Mr. Shubert, America's greatest theatrical manager." And yet we receive signed letters from Texas Guinan from Los Angeles!

> "I would expect to be mobbed at the stage door as I finished my performance, if I deceived the fat burdened folks of America by selling them anything but a high class proven fat reducer."



GOOD FOR A $10.00 YOU GAIN TEN DOLLARS

$10.00 VALUABLE COUPON $10.00

Be sure to use this Coupon within 30 days from the day you receive it.

DO NOT DESTROY WORTH 10 DOLLARS. POSITIVELY VOID AFTER 30 DAYS.

TEXAS GUINAN Inc., Loose Bldg., Los Angeles, Calif

Fig. 3.—This "coupon" gives its recipient the privilege of buying thirty cents' worth of alum and alcohol for only ten dollars!

And whatever you do, do not confuse Texas Guinan's only original fat reducer with anything else you may have heard or dreamed of.

> "All the wafers, pills, powders, miracle dope, rubber jackets, rollers, weakening baths, and willy-nilly what nots, are a hilarious joke to you the moment you begin this treatment and behold with grateful, astonished eyes the marvelous, quick effects."

### LETTER NUMBER FIVE

In spite of all this, and much more; in spite of the fact that Texas inscribes herself "Your fond and faithful friend"; in spite of the promise of the "exuberant happiness" that would follow "the magic of this world-bewildering treatment"; in spite of everything, Letter No. 4 fell on deaf ears. Thus it became necessary for Texas to send Letter No. 5. This epistle lacked the fiery enthusiasm of the previous ones, whether because it was signed "Texas Guinan, per H. D. T., Manager," or because in this letter the price of the treatment is reduced to the ridiculously small sum of $3, it is hard to say. "This offer," you are told, "expires twenty days after you receive this letter." Moreover, "this is the last offer that will be made you; after that date the original price will be $20." To get it at this low price it is necessary to "send the names and addresses of ten fat men or women"; further, "it is understood that you will keep sacredly confidential the special $3 offer made you."

### THE CURE IS PURCHASED

Finally the money was sent and in due time a package came by express containing "Texas Guinan's World-Famed Treatment for Corpulency." This $20 treatment consisted of a quart bottle filled with a muddy liquid, which on standing separated into a pinkish sediment and an almost colorless liquid. The stuff was analyzed in the Association's laboratory, and as a result of the examination, the chemists' report might be summarized as follows:

To make a mixture having essentially the same composition as the "Texas Guinan World-Famed Treatment for Corpulency," take a quart-size fruit jar and put into it:

| | |
|---|---|
| Powdered Alum | 1 pound |
| Alcohol | 10 ounces |
| Water, sufficient to make | 1 quart |

The approximate cost of these materials is 30 cents; selling price, from $20 to $3, according to the ease with which one parts with his money. The chemists' report in detail follows:

### LABORATORY REPORT

"One original, sealed bottle (capacity about 1 quart, $20 size) of the "Texas Guinan World-Famed Treatment for Corpulency" (put up by the Texas Guinan Co., Los Angeles, Cal ) was received at the Association's laboratory and subjected to examination.

Fig. 4.—Photographic reproductions (greatly reduced) of advertisements of some of Cunningham's fraudulent mail-order schemes. In the upper row · The "Della Carson Wrinkle-Eradicator" on the left and "Texas Guinan Obesity Cure" on the right, with the "Princess Tokio Wrinkle-Eradicator" between. In the lower row "Cunningham's Mail-Order School" on *the left, the* "Marjorie Hamilton Obesity Cure" on the right, and "Evelyn Cunningham Bust-Developer" between.

"The bottle contained a heavy sediment (of light pink color) and an approximately equal volume of almost colorless supernatant liquid. On addition of water the sediment readily dissolved. The sample was highly scented with rose water. Qualitatively, the mixture gave tests for aluminum, potassium, sodium (traces of magnesium), iodid, sulphate, alcohol and water.

"The following quantitative data were obtained: 100 c.c. of the well-mixed preparation weighed 112 gm., equivalent to a specific gravity of 1.12; and 100 c.c. of the mixture contained about 60 c.c. of liquid and 51 gm. of solids.

"Some of the mixture was evaporated *to* dryness and the water of hydration removed by heating in an oven at 200 C. The aluminum and sulphate content of this dry powder was determined and found to agree closely with the theory for anhydrous aluminum potassium sulphate (alum), $AlK(SO_4)_2$. From the above examination the preparation appears to be composed essentially as follows:

| | |
|---|---|
| "Alum | 50.2 gm. |
| "Sodium Iodid | 00.16 gm. |
| "Alcohol (absolute) | 29.65 gm. |
| "Water (by difference) to make | 100 c.c." |

### NO ALCOHOL LABEL

In spite of the quantity of alcohol present in the mixture, there was no declaration of the presence of this substance, such as is required by the federal Food and Drugs Act.

The label containing the directions for the use of the stuff we reproduce photographically, omitting only a picture of Texas Guinan in tights, and a "special notice" to the effect that the preparation must positively be shaken before using.

Apparently, the world-famed treatment does not always have the same composition. A specimen of it was sent to us by a New York physician. No alcohol or alum was found in this, but instead a solution of gum, probably tragacanth. It seemed to be of the "vanishing lotion" type. Like the other specimen it had a minute quantity of iodid in it. Moreover, the label on the bottle forwarded to us from New York differed slightly from that on the bottle purchased by The Journal. The label on the non-alcoholic, gummy "cure" bore this statement:

> "By rubbing the fat parts with this liquid you will see that it rubs slowly into the pores; continue rubbing until it disappears and until the skin is apparently dry."

The label of the specimen obtained direct was modified thus:

> "By rubbing the fat parts with this liquid you will see that it quickly dries, leaving a powder upon the surface."

### AND THEN LETTER NUMBER SIX

One might imagine that after they have parted with $20 or $10 or $5 or $3, as the case may be, Texas would be willing to leave her victims in peace. But, no; a few days after the obesity cure has been received, Letter No. 6 arrives. It begins:

> "This is a letter of grave Warning—heed it, and you should have cause for eternal rejoicing—Disregard it, and you may bitterly Reproach Yourself For All Time To Come!"

The point is:

> "*The quantity of reducer sent you must by this time be getting scarce, and I write to warn you about Ordering A New Supply Before It Is Exhausted.*"

Miss Guinan is really quite concerned about the matter:

> "Not having heard from you with an order for a second supply, I have become a *little* worried, my *dear*, that you might make the *terrible* mistake of allowing the bottle to get empty without taking the precaution of having another one on hand. . . . You are now as one who has climbed three-fourths of the way up the *Pinnacle of Happiness—do not falter in your steps, do not hesitate, do not lag, do not doubt or fear.*"

While the "regular price is $20 a bottle to all the world," Texas is magnanimous again and will let her "dear" have repeat orders "for $4 a bottle, or two bottles for $7, or three bottles for $10." On no account must the "treatment" be interrupted; if continued "you will be magnificently reduced to normal proportions," provided—and this is a gem—"you use the treatment until the cause of your fat is overcome."

Then follows a number of testimonials—addresses omitted—leading up to this whirlwind climax:

> "The Golden Goal, The Sweet Reward Is In Sight; It Is All Up To You! It Is For You, And You Alone, To Choose! Success Or Failure? Which, My Dear? Yours with Affectionate Anxiety, Texas Guinan."

### SUMMARY

Those, then, who send $20—or less—for Texas Guinan's "cure" are to rub themselves with a watery-alcoholic solution of alum fifteen or twenty minutes at a time on rising, just before retiring and "as often during the day as desired." It is also suggested that a hot tub be taken twice a day and that white bread, potatoes, sweets and starchy food be omitted from the diet. That by taking hot baths repeatedly, rubbing oneself twenty minutes at a stretch at frequent intervals and dieting strictly, one might be able to reduce weight, is evidently true. That Texas Guinan's *mixture* of alum, alcohol and water has anything whatever to do with the reduction is, just as evidently, not true. In short, "Texas Guinan's World-Famed Cure for Corpulency" is essentially a fraud; as much of a fraud as the "Marjorie Hamilton Obesity Cure" that Cunningham exploited from Denver, or the bust developer and wrinkle eradicator that he sold in Chicago.

At the risk of appearing hypercritical, we reproduce two paragraphs from the order-blank used in purchasing the Texas Guinan "cure."

> "I also buy it with the understanding that it is new and different from any other treatment in the world that you ever heard of being advertised, and that there are no exercises of any kind with it, no dieting of any description, and that I may eat all kinds of foods I desire while taking it.
>
> "And I buy it with the still further understanding that worthless massage is unnecessary, and that in no part of your treatment is there any physical culture of any description, no internal bathing or enemas, no worthless, harmful creams to rub upon the skin or body, that there are no Turkish baths, no apparatus of any kind, no bandages, no belts, no garments, no body-wrecking sweat baths, no medicine, pills or internal stuff to swallow, no special foods and no obesity biscuits—nothing to take internally."

Possibly a mixture of alum, alcohol and water is "new and different from any other treatment in the world," for obesity. It cannot be said, though, that there are "no exercises of any kind," when the purchasers are explicitly instructed to rub themselves for fifteen or twenty minutes at a stretch. The statement that there is "no dieting of any description" and that the person using the nostrum "may eat all kinds of food," is also untrue, in the light of what appears on the label, which suggests a strict diet. A careful reading of the second paragraph given above will show that while many of the statements are technically true, they are essentially false.

It is a sorry commentary on our laws that a man whose business has been essentially one of fraud and deceit for years past, can continue to swindle the public with apparent impunity. The federal authorities took action in the case of Marjorie Hamilton, but as yet have not pushed the thing to completion. The Journal's thorough-going exposure of this particular swindle—and the publicity which the papers of the country gave The Journal article—killed it, financially. All that Cunningham needed to do, however, was to transfer his offices to another state and start up under another name. His stock in trade are impudence and mendacity; his clientele, the gullible. The federal machinery of necessity moves slowly, and it should be unnecessary to invoke federal aid in prosecuting a fraud of this kind. When Professor Samuels, the Wichita quack, attempted to operate his fraud-factory in Detroit, the local authorities took the thing in hand and made Michigan too hot for him. The local authorities of Los Angeles can do the same thing for Cunningham.

# Correspondence

## The Better Control of Ophthalmia Neonatorum

*To the Editor:*—In The Journal, Aug. 30, 1913, p. 634, Dr. A. Jacobi, the retiring president, states that "in 108 cases of ophthalmia neonatorum that are reported by various eye clinics, sixty-two patients were attended by physicians, forty-three by midwives, and three by neighbors . . . It so happened that all the cases of total blindness occurred in the practice of physicians." Yet we find that the punitive measures of the proposed bill are directed against the midwife most of all. Truly, there is plenty of material for the lawyer of sporting instinct, keen for employment in any possible claim against the opulent physician and the dividend-paying hospital association, but in the main it is the midwife that is to be regulated.

About six years ago I vainly tried to interest the health authorities of Cleveland in a consistent policy of saving the eyes of the newly-born. Instead, there followed an antimidwife crusade, resulting in jailing a baker's dozen of them—and nothing else. The mountains labored and brought forth a most ridiculous mouse.

Dr. Jacobi well insists on the training of midwives, sweeping aside the childish fears expressed in some quarters that the midwife might eventually compete with the physician. There is not a man in practice but knows that our immigrant citizens and too many others, employed at small wages, have not the means to employ a physician, let alone a nurse subsequent to accouchement; nor do they seem to conform to the American style of restricted families. It is this class of our citizenship which necessarily depends on the midwife. Our place is to bring about a system of training the midwife, not to jail her.

Whether or not the employment of a general practitioner as an accoucheur would eliminate ophthalmia neonatorum is a question that remains unanswered. My observation and experience do not incline me to an affirmative opinion. Abroad, especially in the rural districts, and in the city slums, where according to the tabulated returns of vital statistics, more than 75 per cent. of all confinements are assisted by midwives, not a single eye is lost from the disease. Here enters, too, a matter of professional difficulty—ethics, I had almost said. Take the busy physician, with a long calling-list. Attending, among others, a patient with scarlet fever, diphtheria or erysipelas, does he invariably take the time, granting the inclination, to bathe and to change his attire completely before calling on his next patient in what may perhaps be a confinement case? Is it not possible that contagion is carried in this way? It is well that we do not know! What we do know is that many a busy physician, impatient at the delays of natural childbirth, resorts to artificial aids; and again we should account ourselves fortunate in failing to know what damage accrues to the patient because of our "advanced" knowledge and dexterity.

Every reader knows that with all her antiquated ways Europe has but a tithe of women suffering from the diverse female troubles to which America is heir, and that our daily diet of laparotomies and exsected ovaries, by selfstyled "surgeons," is a rarity on the other side. This condition is almost entirely due to the employment of the midwife, educated and trained in her special work, supervised by competent practitioners, and, above all, grounded in the elementary instruction that on no account may she pass beyond the limits of her sphere, being specifically directed to call the physician at the first symptom of any abnormal condition. This course, while inuring to the immediate rectification of any trouble, automatically settles the fear of possible "competition."

What a splendid corps of midwives might be produced in America under proper conditions! Our women, intelligent, quick to learn and to observe, pliable to training and conscientious in their work, would make splendid material, while the prominence and responsibilities attaching to the work would raise it in the public opinion as one most desirable, yielding, at the same time, sufficient remuneration without imposing great burdens on the poorer among our citizenship. Such a step, it may well be believed, would settle the matter of lying-in homes and hospitals.

Finally, inasmuch as most of the victims of ophthalmia neonatorum come from the slums, and in view of the fact that the disease is the result of the ignorance of parents or prospective parents, I have long been convinced that appropriate instruction by way of public lectures and in other ways will almost wholly eliminate this crime against humanity.

There remains a word to be said about Section 4, Article 3, in the proposed bill, prepared under the auspices of the Council on Health and Public Instruction of the American Medical Association (The Journal, June 21, 1913, p. 2004), providing for the gratuitous distribution by the state board of health of a scientific prophylactic to physicians. There is no physician who would grudge the few pennies for investment in a bit of silver nitrate, while, on the other hand, the state should not be put to a considerable expense for purchases of medicine, packing and mailing. But that is an insignificant matter in comparison with the importance of the bill itself.

James Stotter, M.D., Cleveland.

## Convenient Rule for Dividing Doses

*To the Editor:*—I wish to submit a method which will save the doctor and nurse a good deal of time in administering drugs. If the physician wishes to divide a dose, such as a tablet containing a fraction of a certain weight (grain or gram) so as to give a smaller fraction, the following rule may prove convenient: Dissolve the larger dose in as many volumes of water (minims or cubic centimeters) as equal the denominator of the smaller fraction and give of this solution a number of volumes (minims or cubic centimeters) equal to the denominator of the larger fraction. Thus, if we have ⅛-grain tablets of morphin sulphate and wish to give 1/64 grain, we measure 64 minims of water, in which we dissolve the ⅛-grain tablet. Then by taking 8 minims for injection we give the required 1/64 grain.

MICHAEL S. AARONSON, M.D., New York.

# *Queries and Minor Notes*

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

## MARSDEN'S PASTE IN EPITHELIOMA

*To the Editor:*—1. Please give the formula of Marsden's Paste.

2. How often usually should it be applied to an epithelioma of ordinary size, one, for instance, as large as a small chestnut? How should it be applied, and how often, or do conditions of the neoplasm determine these points?

3. Why could I not use it on an epithelioma of the ala of the left nostril of an old man? This growth is about the size already mentioned and is getting larger. It is causing no discomfort. There are no metastases and the growth appears to be absolutely local. The patient cannot avail himself of opportunities which are not here, as radium, etc., and prefers to avoid the knife if possible.

FRANK P. NORMAN, M.D., Greenville, Ga.

ANSWER.—1. Marsden's paste consists of powdered acacia 1 part and arsenious acid 1 or 2 parts by weight, which are mixed at the time they are to be used with enough water to make a paste of the consistency of a firm ointment. If deep destruction of the tissue is necessary it is better to use the stronger mixture. If the lesion is relatively shallow in comparison with its area, the mixture of equal parts of arsenious acid and acacia is sufficient. In ulcerating lesions the stronger paste is preferable, because the eschar is formed more quickly and limits the absorption of arsenic.

2. The paste is applied in a thick layer over the area to be destroyed, and should extend beyond the apparent border of diseased tissue. It should be left in position until a white eschar is produced; this requires from eight to twenty-four hours. After the eschar forms, it should be dressed surgically. The slough will separate in from five to seven days, and if the treatment is properly carried out there remains a healthy granulating wound which heals in about a week and leaves a relatively small scar. After separation of the slough and healing of the wound, if any areas of epithelioma remain the treatment can be repeated as at first. Nodules of epithelioma that are covered by epidermis must be denuded by the curet or caustic potash or some similar agent before the application of an arsenic paste, for arsenic does not destroy horny epidermis.

3. If it is going to be used on an exuberant tumor on the ala nasi, such as described, the excess of epitheliomatous tissue should first be curetted away and the paste applied as above described to the base. It is probable that the layer of healthy tissue under the epithelioma is thin, if the tumor has not involved the entire thickness of the ala nasi, so that the ala nasi will probably be destroyed in the procedure.

In proper cases epitheliomas can be destroyed radically by such a paste, but it is not a method of preference in most cases and should be undertaken with caution.

## DELAFIELD'S HEMATOXYLIN—EHRLICH'S ACID HEMATOXYLIN

*To the Editor:*—Please give methods of preparation of Delafield's hematoxylin and Ehrlich's acid hematoxylin.

W. H. ENDERS, M.D., Jackson, Mich.

ANSWER.—The methods of preparation are as follows:

Delafield's Hematoxylin: To 400 c.c. of saturated solution of ammonia-alum (that is, about 1:11 of water) add 4 gm. of crystallized hematoxylin dissolved in 25 c.c. of strong alcohol. Leave it exposed to the light and air in an unstoppered bottle for three or four days. Filter, and add 100 c.c. of glycerin and 100 c.c. of methyl alcohol ($CH_4O$). Allow the solution to stand (uncorked) until the color is sufficiently dark, then filter.

Ehrlich's Acid Hematoxylin: Water 100 c.c., absolute alcohol 100, glycerin 100, glacial acetic acid 10, hematoxylin 2 gm., alum in excess. Let the mixture ripen in the light (with occasional admission of air) until it acquires a dark red color. It will then keep, with constant staining power, for years, if kept in a well-stoppered bottle. It is very appropriate for staining in bulk, as overstaining does not occur.

## LIABILITY FOR MEDICAL AND SURGICAL CARE OF PAUPERS IN ILLINOIS

*To the Editor:*—Can you give me information in regard to the Illinois laws on the medical and surgical care of paupers and near paupers? What are the duties of the township supervisors (overseers) in providing county help for sick paupers in the rural districts of Illinois where no regular county physician is appointed?

T. A. J., Illinois.

ANSWER.—Chapter 107 of the Illinois Revised Statutes, Paragraph 1732, provides that relatives of any pauper are first liable for his care, which would include necessary medical and surgical treatment. By relatives are meant children, parents, grandparents, cousins, uncles, aunts, etc., the nearer relatives being liable first. In case a township supervisory or overseer employed a physician to attend the pauper, the physician might present his bill to the overseer who would notify the court, and the relatives, if able, would be compelled to pay for such services. In case they were unable to pay, the physician's compensation would come from the township or county poor-funds.

## PRIVILEGED COMMUNICATIONS IN ILLINOIS

*To the Editor:*—I keep my account on one side of a sheet of paper and the case report on the other. I have seen a statement to the effect that accounts kept in this manner cannot be used in court in an attempt to collect, because of the fact that the record of the case would be considered a privileged communication. What is the status of this matter?

P. E. B., Illinois.

ANSWER.—There is no statute in Illinois covering the question of privileged communication between physician and patient. By the common law, the rule of privileged communications applies only between lawyer and client and such rule must be created by statute in all other relations. (See Wigmore on Evidence, Paragraph 2381, *et seq.*) In states having such a statute covering the relation of physician and patient, it might apply to an account of the character above defined, but it would depend on the interpretation of the court.

## EARLY DEMONSTRATION OF WASSERMANN REACTION

*To the Editor:*—1. How soon after the initial lesion of syphilis is a Wassermann demonstrable?

2. Is it true that a Wassermann is negative until after the secondary stage?

J. B. SPALDING, M.D., Kenosha, Wis.

ANSWER.—1. The reaction has been observed five days after the appearance of the initial lesion and can be elicited in a majority of cases after the lapse of fifteen days.

2. No.

## ELLIOT'S OPERATION FOR GLAUCOMA

*To the Editor:*—Please describe Elliot's operation for glaucoma.

J. T. LITTLE, M.D., Pittsburgh, Pa.

ANSWER.—Lieut.-Col. R. H. Elliot, of the (British) Indian Medical Service, Madras, a recent visitor to America, has revived (since 1909) and much improved a half-forgotten method of trephining the sclerocornea for the relief of increased tension in the various forms of glaucoma. Fergus reported the operation a little earlier than Elliot, but he has not had the wide experience of the Anglo-Indian, who has probably evolved a better procedure. Dr. Elliot has written a practical little work on the subject; in it he describes his operation which, in brief, is as follows: The operation may be performed under the local influence of cocain and epinephrin dropped into the sac.

The patient looks down, and a large triangular flap of conjunctiva is dissected up from above the cornea, the attached base of the triangle lying at the sclerocorneal margin. Experience has shown the importance of dissecting this flap right up to the limbal attachment of the conjunctiva. The flap is turned down on the cornea. The spot selected for the trephining should be in the cornea as much as possible, and should be prepared by using the scissor points freely, either cutting or scraping or both, right down to the scleral coat. It is important that no conjunctival tissue be left; otherwise it will catch in the trephine and tend to draw the flap into the latter as it is working. The operator should never pull on the flap, but simply steady the globe by pressing on the cornea through the down-turned flap. This is sufficient to keep the eye at rest and in the proper position. The trephine is used with quick, light movements, and care is taken that its first application suffices to bite into the sclera, before it is raised to see the progress made. Once a clean ring is thus started, it is easy to replace the trephine in it. As soon as the anterior chamber is tapped, aqueous fluid wells up alongside the trephine; even apart from this, there is a curious sucking sensation which tells one the trephine is through. Moreover, the patient often helps, by a slight movement due to the pain (seldom severe) which attends the completion of the section. The conjunctival flap is replaced *in situ* to see whether or not the iris is in position. If it is, and if there is no bulging of its base into the wound, the eye is at once closed. It sometimes happens that the iris bulges into the section the moment the disk is cut through; if so, it is snipped with scissors to let the aqueous fluid escape, and it then often goes back of itself. If it does not, then an iridectomy is performed. As a rule, a very small and peripheral section of the membrane suffices; more rarely it is necessary to make the iridectomy complete. It is well to instil physostigmin (eserin) drops into the eye after operation, if for any reason it is feared that a prolapse may take place. As a rule, no drops whatever are used immediately after the operation.

Elliot has somewhat modified his early operation by continuing the elevation of the tissues into the clear cornea—splitting the latter with a dull paracentesis needle or similar instrument—and he places emphasis on entering the trephine so that the corneal section shall be first made and a little hinge of tissue be formed toward the sclera. This hinge and the iris periphery may often be cut through by one snip of the scissors.

### CONTAGIOUSNESS OF SMALL-POX

*To the Editor:*—Please answer the following questions:

1. At what stage of the disease is small-pox most contagious, or is it contagious at all stages of the disease?
2. How contagious is the exfoliated material?
3. Is the expired breath contagious through all of the stages of the disease?

L. P. Barbour, M.D., Rocky Ford, Colo.

Answer.—1. Small-pox is contagious from the earliest active stage to the end of convalescence, and possibly even during the stage of incubation.

2. The exfoliated matter is very contagious and very tenacious of its infectivity. Its vitality is retained after the patient's death, and the room occupied by a patient, the bedding and articles of furniture all serve to convey the disease unless thoroughly disinfected.

3. Probably.

### EFFECT OF CUTTING THE VAS DEFERENS

*To the Editor:*—Please state whether or not cutting the vas deferens affects sexual desire.

J. A. Boyer, M.D., Carmi, Ill.

Answer.—The effects of cutting both vasa have been extensively observed in men as well as in animals. Observers are agreed that no perceptible change in sexual desire or power results therefrom. This conclusion accords with the familiar clinical observation that occlusion of both ducts through bilateral gonorrheal epididymitis does not in the least impair the subject's sexual desire or power. He does not even suspect any genital irregularity until search for the cause of the wife's failure to conceive reveals the absence of spermatozoa from the semen.

### SUBSCRIPTIONS FOR FOREIGN JOURNALS

*To the Editor:*—Please inform me if there is a place in America where one can subscribe for the *Wiener klinische Wochenschrift*, and also the price of the annual subscription.

J. Curtis Lyter, M.D., Moberly, Mo.

Answer.—The prices for subscriptions to all the exchanges listed in our Current Medical Literature Department were given in the Index Number of The Journal, June 28, 1913, p. 2097, and will be republished with the Index, December 27 next. The *Wiener klinische Wochenschrift* is there given as costing 24 marks a year. This is about $6, plus postage.

Advertisements of persons who make a specialty of taking subscriptions for foreign journals appear in nearly every issue of The Journal.

### COLLOIDAL PALLADIUM

*To the Editor:*—A physician here told me that he saw in The Journal a short time ago an article on the increasing of oxidation and the absorption of adipose tissue by the use of a *Colloidal Palladium* (he was not certain about the name of the metal used). Can you give me the number of The Journal containing the article described?

Lydia Allen DeVilbiss, M.D., Fort Wayne, Ind.

Answer.—Colloidal Palladium (Leptynol) was introduced by M. Kauffmann (München. med. Wchnschr., 1913, lx, 525, 1260), who states that it is related to the platinum group. The author performed experiments on himself and used the substance in other cases, he claims, with success. No other reports concerning this substance are available. It is apparently one of the many thousand proprietaries produced abroad in the past year and put on the market after meager experimental work.

### LITERATURE ON FIELD HOSPITALS

*To the Editor:*—Please refer me to literature giving plans for field and camp hospitals, and describing how they are conducted.

J. A. Rosenberger, M.D., Big Creek, Cal.

Answer—Following are references to recent articles on field hospitals:

Baketel, H. S.: Field Hospitals in Peace and War, *Mil. Surgeon*, November, 1913.
Reno, W. W.: Proposed Method of Pitching and Striking a Field Hospital rapidly, *Mil. Surgeon*, April, 1913.
Boaz, J. J.: Hospitals in the Field, *Mil. Surgeon*, November, 1910.
Lovering, P. A.: The Hospital Camp at Norfolk, Va., *U. S. Nav. Bull.*, October, 1909.

# *Medical Economics*

This Department Embodies the Subjects of Post-graduate Work, Contract Practice, Legislation, Medical Defense, and Other Medicolegal and Economic Questions of Interest to Physicians

## HEALTH DIRECTION IN THE PUBLIC SCHOOLS

C. P. McCord, Medical Inspector of Schools at Albany, N. Y., in a paper read before the Fourth International Congress on School Hygiene at Buffalo, says that we are living in the renaissance of science as applied to society. Interest in the growing child is manifested in laws concerning child-labor, infant-welfare work, school medical inspection and school nurses. Compulsory education has placed approximately twenty million children under a daily routine in the schools which is often far from being conducive to good health and normal development. Modern medical inspection in the schools dates back nineteen years, but its importance in our educational system is constantly increasing.

McCord believes that school medical inspection constitutes a specialty as much as laryngology or otology, but so far only two American medical colleges offer courses on social pediatrics in connection with instruction in the diseases *of children of* school age. In view of the great extension of school medical inspection there is a great need of well-trained physicians along this line. McCord believes that full-time men should be employed, preferably those having some experience as executives in school work, together with a first-class medical training with a knowledge of the elements of the specialties. They should have a fair outlook on pedagogic and sociologic problems, and should be paid adequate salaries. To afford the best results there should be a sufficient number of nurses to insure a daily visit to every school, which would mean one nurse to about fifteen hundred children. Adequate records should be kept. A good working reference library along medical, psychologic and sociologic lines should be provided.

McCord says that the medical officer should in no way usurp the privileges of the family physician. Much of the opposition to school inspection arises from the profession itself, and this is a greater drawback to effective work than is the opposition of parents to what they often believe to be an infringement on their rights as parents. It is the duty of the medical director always to refer cases to the family physician, who in necessary instances will refer them to a proper specialist. The opposition of the profession to a medical director in the schools arises from the fear that he will favor particular physicians or that he will treat or suggest treatment. The proper understanding of the aims of a well-equipped medical director will dispel this idea. The full-time man removes the danger that the inspector may "work" his position to increase his private practice.

When medical inspection is part of the educational system the question of the relation to the local board of health arises. Most cordial relations should, of course, exist, but it is chiefly the acute contagious diseases among schoolchildren which will fall under the authority of the board of health. In Albany, where McCord is director, the plan is that all such diseases are reported by telephone to the board of health, and in turn each morning the office of the medical inspector receives the report of all such cases known to the board of health.

McCord says that in view of the recent researches on measles and scarlet fever, the question arises as to whether or not the period of exclusion for these diseases might not be shortened materially. In the matter of diphtheria he believes that there should be a more rapid enforcement of the new rule requiring for release two negative cultures on two successive days. McCord's suggestion for lessening the spread of diphtheria would be to make cultures of every sore throat, and in instances in which a case of diphtheria develops to culture at once the throat of every child in the class and exclude the carriers.

The five chief highways to health in the public schools are medical inspection, school hygiene, personal hygiene, physical training and welfare work; and in the department of school inspection in Albany, as organized by McCord under the statute of New York making medical inspection of schools compulsory, the foundations have been laid for effectively carrying out these five requirements. The system was initiated in March, 1913. A laboratory has been established with facilities for complete medicopsychologic examination of backward children, and special classes have been provided for such children. An important feature of medical inspection is the work of the nurses. In Albany the city has been divided into districts with a nurse in every district. Every school receives a visit every other day. Acute or contagious diseases are first dealt with and the other children are thus protected. After these cases are attended to, routine examinations for physical defects are made and parents are notified, with the request that the child in question be taken to the family physician.

As to the practical results in Albany, since April, 1913, forty-eight operations have been performed by Albany physicians for the correction of physical defects. Over 50 dental treatments have been secured, 150 children have been provided with eye-glasses and hundreds of children with contagious and parasitic diseases have been excluded until cured. The inspections have shown defective vision in 20 per cent., enlarged tonsils in from 6 to 12 per cent., nasal obstructions in from 12 to 20 per cent., decayed teeth in from 50 to 80 per cent., nervous disorders in from 5 to 20 per cent., orthopedic defects in 20 per cent., skin diseases in from 1 to 15 per cent., mental defects in from 1 to 2 per cent., and defective hearing in from 2 to 5 per cent. One great object of the medical inspection is to place the responsibility with the parent for obtaining advice from the family physician. An interesting feature of the Albany plan is the blank for recording the medicopsychologic laboratory examination, which includes the history, examination, and sociologic, psychologic and educational data.

---

## THE PUBLIC HEALTH SITUATION IN ATLANTA

Atlanta, Ga., is a progressive and rapidly growing city of 175,000 inhabitants. The public-spirited citizens composing the Chamber of Commerce of Atlanta, recognizing that the health of a city is its greatest asset and one of the requisites for attracting people and industries, made provisions for a survey of the public-health situation. This survey was conducted by the Department of Surveys and Exhibits of the Russell Sage Foundation, which has recently made its report. This report in many of its features, in which health conditions in Atlanta are criticized, would undoubtedly apply to most of our cities. It is therefore not to be considered purely as a criticism or condemnation of conditions in Atlanta, but rather as a valuable guide to the improvement of health conditions generally. That, of course, was the end sought by the citizens in obtaining this survey.

One of the first features of the report is that of preventable diseases, from which it is shown that 15.6 per cent. of the whole mortality (about 3,000) of the city in 1910 was due to eight well-known infectious diseases which are generally admitted to be preventable. Adding four other diseases, diarrhea, meningitis, pneumonia and puerperal fever, which are probably preventable under ideal conditions, the total deaths (1,042) from preventable diseases was 35.5 per cent. of the total mortality.

Inasmuch as the prevention of such diseases is one of the chief functions of the health organization, the report discusses the present organization of the health board of Atlanta. The board of health consists of ten members. This board directs the work of two separate organizations, the division of sanitary inspection, which is occupied with the collection and disposal of garbage, cleaning of streets and the engineering aspects of health work, and the department proper, which is in charge of a health officer hired and directed by the board. The board maintains a laboratory, a detention hospital for contagious diseases and a tuberculosis sanatorium, and is engaged in the registration of vital diseases, the control of communicable diseases, milk and dairy inspection, meat and market inspection, mosquito reduction, plumbing inspection and medical relief to the poor. The appropriation for carrying on this work is $80,000 yearly, which is less than 23 cents per inhabitant per year, which the report regards as considerably below the minimum requirement for a modern effective department. This is the great criticism which applies to practically all municipal health departments at present.

The system of reporting vital statistics is criticized not because it is inadequate, but because of lax enforcement. It is said that births must be reported promptly if any baby-saving work is to be attempted, and that deaths should be reported not only promptly but with accurate and adequate information. Examination of 349 death certificates filed during May, 1913, showed the statement of cause to be satisfactory in only 181. The remaining 168, or 48 per cent., were found to be incorrect, incomplete or indefinite, which, as the report says, is not only in violation of the law, but is a testimonial of ignorance and carelessness which is a serious reproach to the local medical profession. This comment again would apply to almost any other city.

Criticism is made that measles, whooping-cough, erysipelas, chicken-pox, typhus fever and pellagra, which were formerly reportable, were dropped in 1911 from the list of reportable diseases at the suggestion of the Fulton County Medical Society. Diphtheria, scarlet fever, small-pox and cerebrospinal meningitis are reported satisfactorily, but typhoid fever and tuberculosis are said to be reported in only about half of the cases. Only a few of the typhoid patients are visited and no steps are taken to follow up tuberculosis. Diphtheria patients are released ten days after the disappearance of the clinical symptoms, and attention is called to the fact that it is a better practice to release only after two successive negative cultures. Laboratory diagnosis in tuberculosis and diphtheria is offered by the department, but the work is hampered by the lack of funds, and it is said that the city neglects a definite opportunity to purchase public health.

Milk and dairy inspection is likewise provided for in a comprehensive ordinance covering inspection of dairy farms, depots, etc., and prescribing milk standards and proper temperature and bacteriologic standards; but only two dairy inspectors, one bacteriologist and an assistant are provided, which is an entirely inadequate force for the work to be done.

Meat and market inspection is commented on in the report, although no provisions are made for the chemical detection of adulterations of food.

Mosquito reduction is fairly well provided for, but the health officer believes that a larger sum of money could be profitably spent.

The criticism is made that nearly one-sixth of the department's appropriation is spent on plumbing inspection, which is a matter now considered to have slight hygienic significance, and it is said to be unfortunate that twice as much is spent on this department as for the control of communicable diseases.

In referring to the defects in the present organization of the board, it is said that the board's system of health-department control is a relic of the days in which health work was largely a matter of nuisance abatement and emergency steps in the face of epidemics of small-pox, etc. Public-health work has become technical and it is now considered wiser to hire a competent specialist in public-health work. The problems of disease and statistics are beyond the field of experience of the members of the board.

It is also pointed out that the sanitary division carries on certain work which properly belongs to the health department, such as the supervision of privies and dry closets, which is work of distinct hygienic importance, as is that of the inspection of private wells, a service now entirely omitted.

Among the "neglected opportunities" considered in the report is that of lessening the death-rate among infants under 1 year of age, of which there were 521 in Atlanta in 1910. In other cities this problem has been attacked by requiring proper reporting of births and the visiting of cases by health department nurses. Midwives are examined and regulated, and infant-welfare stations are established in congested districts which supply pure milk and cheap ice. Atlanta has not taken any of the above-mentioned steps, but a number of private organizations have been carrying on this work on a limited scale.

The restriction of tuberculosis, it is stated, offers another of the largest opoprtunities for health improvement. In Atlanta, many of the elements of a well-rounded program for the improvement of conditions with regard to tuberculosis are present, but they need to be brought together and augmented. The health department receives reports of cases (though only partially complete) and maintains a sanatorium, and the antituberculosis society maintains a clinic, investigates cases and furnishes certain nursing facilities. The cooperation between these two organizations is not close enough.

One of the chief opportunities for betterment recommended in the report is that of dispensary service for the benefit of the poor, among whom much sickness occurs, a greater portion of which is of the communicable and preventable variety. These patients, if not treated, serve as reservoirs, or incubators of infection, and purely as a matter of economy, if nothing else, should be found and cured. The most effective way in which this can be done, it is stated, is through a free health department dispensary which becomes a recognized center not only for medical treatment but also for the dissemination of all kinds of sanitary knowledge.

A good housing law is recommended as being especially desirable for Atlanta with its large colored population and congested living conditions, which make the spread of infectious diseases easy. It would produce a great improvement also in the houses of the better classes, eliminating dark rooms and insuring proper sanitary arrangements, etc.

The report says of the negro, who constitutes a larger proportion of the population than in many Northern cities, that he may be regarded as a hygienic liability, but at the same time represents a hygienic opportunity because he represents an opportunity to reduce greatly the community's stock of infectious diseases. At present in Atlanta practically no attention is paid to infectious diseases among the negroes, and no isolation hospitals are open to them.

The recommendations and conclusions of the report embody the correction of the conditions criticized above and as far as posible a reorganization of the health department, centering greater authority and responsibility in a competent health officer, and above all, providing adequate appropriations for carrying out the well-known problems of city hygiene and sanitation.

As of course is to be expected, Atlanta presents special problems, which the survey has revealed, but, as we have stated, in the main the criticisms of almost every condition mentioned will apply to practically every city in the land. The fact that a survey has been demanded by the citizens of Atlanta is the best assurance that progress is bound to be made along these lines.

## COMING EXAMINATIONS

ALABAMA: Montgomery, Jan. 13. Chairman, Dr. W. H. Sanders, Montgomery.

ARIZONA: Phoenix, January 3. Sec., Dr. John Wix Thomas, 200 National Bank of Arizona Bldg., Phoenix.

COLORADO: State Capitol, Denver, January 6. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

ILLINOIS: The Coliseum Annex, Wabash Ave. and 16th St., Chicago, Jan. 14-16. Acting Sec., Amos Sawyer, Springfield.

INDIANA: Room 56 State House, Indianapolis, Jan. 13-15. Sec., Dr. Wm. T. Gott, 56 State House, Indianapolis.

IOWA: The Capitol Bldg., Des Moines, January 6-8. Sec., Dr. Guilford H. Sumner, Capitol Bldg., Des Moines.

KENTUCKY: Armory, Louisville, Dec. 11-13. Sec., Dr. J. N. McCormack, Bowling Green.

MARYLAND: Homeo., St. Luke's Hospital, Baltimore, Dec. 15-16. Sec., Dr. O. N. Duval, 1817 N. Fulton Ave., Baltimore.

MINNESOTA: State University, Minneapolis, January 6-9. Sec., Dr. Thos. S. McDavitt, 814 Lowry Bldg., St. Paul.

NEW HAMPSHIRE: State House, Concord, January 6-7. Regent, Mr. H. C. Morrison, State House, Concord.

NEW MEXICO: Santa Fe, Jan. 12. Sec., Dr. W. E. Kaser, East Las Vegas.

NORTH DAKOTA: Grand Forks, January 6. Sec., Dr. G. M. Williamson, Grand Forks.

OKLAHOMA: Oklahoma City, Jan. 13. Sec., Dr. John W. Duke, Guthrie, Okla.

OREGON: Portland, January 6-8. Sec., Dr. L. H. Hamilton, Medical Bldg., Portland.

SOUTH DAKOTA: Capitol Bldg., Pierre, Jan. 13. Sec., Dr. Park B. Jenkins, Waubay.

VERMONT: Montpelier, Jan. 13-15. Sec., Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, Dec. 16-19. Sec., Dr. Herbert Old, Norfolk.

WASHINGTON: Spokane, January 6-12. Sec., Dr. F. P. Witter, Traders' Block, Spokane.

WISCONSIN: Madison, Jan. 13. Sec., Dr. John M. Beffel, 3200 Clybourn St., Milwaukee.

## Louisiana October Report

Dr. A. B. Brown, secretary of the Louisiana State Board of Medical Examiners, reports the written examination held at New Orleans, Oct. 27-29, 1913. The number of subjects examined in was 10, the total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 27, of whom 16 passed and 11 failed. Four candidates were licensed through reciprocity. The following colleges were represented:

PASSED

| College | Year Grad. | Per Cent. |
|---|---|---|
| Birmingham Medical College | (1913) | 85.2 |
| University of Alabama | (1913) | 82.9 |
| Chicago College of Medicine and Surgery | (1913) | 83.7 |
| Illinois Medical College | (1910) | 79.6 |
| Tulane University, (1897) 77.1; (1910) 84; (1913) 78.7; 82.4; 87.6; 89.7; 90.1; 90.8. | | |
| Jefferson Medical College, Philadelphia | (1913) | 82.6 |
| Memphis Hospital Medical College | (1913) | 79.8 |
| University of Tennessee | (1913) | 77.4 |
| Fort Worth School of Medicine | (1911) | 86.4 |

FAILED

| College | Year Grad. | Per Cent. |

LICENSED THROUGH RECIPROCITY

| College | Year Grad. | Reciprocity with |
|---|---|---|
| University of Illinois | (1912) | Illinois |
| University of Louisville | (1912) | Kentucky |
| Baltimore Medical College | (1912) | Maryland |
| University of Michigan | (1912) | Michigan |

One candidate, a graduate of the Hahnemann Medical College, Chicago, in 1906, was licensed through reciprocity with Illinois by the Homeopathic State Board of Medical Examiners of Louisiana, November 3, 1913.

The following questions were asked:

PATHOLOGY

1. (a) What is an infarct? (b) What is an anemic infarct? (c) What is a hemorrhagic infarct? 2. Describe the process of healing wounds by first intention. 3. Name the different forms of pus-producing cocci, and state which of these are the most virulent. 4. (a) What is suppuration? (b) What is leukocytosis? 5. What changes occur in joints following gonorrheal metastasis? 6. Describe the pathology of acute osteomyelitis. 7. What are the pathological changes found in the small intestine in typhoid fever? 8. Describe the gross pathology of acute lobar pneumonia. 9. Describe the

pathology of pyonephrosis. 10. Describe the pathology of arteriosclerosis.

### ANATOMY

1. Name boundaries, anterior and posterior of axilla. 2. Describe the thoracic duct. 3. Give origin and structures supplied by the glossopharyngeal nerve. 4. Describe the Y or iliofemoral ligament. 5. What is connective tissue? Where is it found? 6. Name ligaments of ankle joint. 7. Describe the pleura. 8. Describe the arteries and veins passing to and from the kidney. 9. Give component parts of spermatic cord. 10. Describe the relations of the peritoneum to the bladder.

### PHYSIOLOGY

1. What is invertin, and what part does it play in digestion? 2. What is an internal secretion; name the more important organs concerned in the process of internal secretion. 3. What are the principal waste products of metabolism and through what channels are they excreted? 4. What are the average proportions of the principal constituents of normal human milk? 5. What kind of nerve impulses are carried through efferent and afferent nerve fibers? 6. What is the result of injury to, or removal of, the semicircular canals? 7. Name the nerves concerned in the constriction and in the dilatation of the pupil of the eye. 8. State briefly what is understood by diapedesis and phagocytosis. 9. What factors are concerned in the second sound of the heart and where is this sound best heard? 10. Relative to external respiration, state briefly what is understood by (a) tital air, (b) complemental air, (c) reserve air, (d) residual air.

### CHEMISTRY

1. What are the principal allotropic forms of carbon? 2. How does carbon dioxide act as a poison? 3. What is an unorganized or soluble ferment? 4. Name the soluble ferments of the body. 5. What are the tests for starch? 6. What caution should be observed in testing urine for sugar? 7. What are ptomaines, and name some of the best known ptomaines? 8. What is the principal salt of silver used in medicine, and what are the properties of this salt? 9. What are fats, and name the principal animal fats. 10. (a) Is elementary arsenic poisonous. (b) how does arsenic prove poisonous, (c) which is the most common poisonous compound of arsenic?

### THERAPEUTICS

1. (a) What are mydriatics? (b) Name them. 2. Name the principal drugs used for the reduction of blood-pressure. 3. (a) What are cardiac stimulants. (b) Name some of the best known drugs used for this purpose. 4. Describe the physiologic action of the diuretics. 5. How would you treat a case of acute opium poisoning? 6. What are the antidotes for arsenic? 7. Describe the treatment of valvular disease of the heart with failing compensation. 8. How do substances act by counter-irritation? Name some of the best known counter-irritants. 9. Describe the action of antidiphtheric serum in a case of diphtheria. 10. What are the physiologic actions of the salts of cinchona?

### PHYSICAL DIAGNOSIS

1. What are the types of normal respiration, and what conditions would cause alterations of same. 2. What conditions influence the production and variation of pitch? 3. Define dyspnea, and state the types and causes of same. 4. Summarize the points of differentiation between pleuritic friction sounds and bronchitis. 5. Describe the natural heart sounds, and the causes of each. 6. Describe the characteristics and significance of the various kinds of arterial pulse. 7. What are the physical signs of pericarditis with effusion. 8. Differentiate cardiac hypertrophy and cardiac dilatation. 9. Give the physical signs of combined aortic and mitral insufficiency. 10. Describe the physical signs of ascites and those of cystic disease of the ovary.

### SURGERY

1. Give treatment of a compound fracture of humerus. 2. Give symptoms and treatment of tubercular hip joint. 3. What operative measures may be indicated in exophthalmic goiter? 4. Differentiate between enlarged inguinal glands, hernia and hydrocele. 5. Give diagnosis and treatment of epithelioma of lower lip. 6. Give symptoms of acute osteomyelitis. 7. Describe the operation of posterior gastro-enterostomy. For what condition is it most frequently performed. 8. Give symptoms, diagnosis and treatment of tubercular kidney. 9. Give signs, symptoms and treatment of depressed fracture of skull. 10. Describe Colles' fracture. How is it generally produced and how should it be treated.

### OBSTETRICS

1. (a) What are the causes of prolonged first stage of labor; (b) dangers; (c) management? 2. Discuss in general the principal drugs used to hasten labor. 3. What are the prerequisites, indications and contraindications for the use of forceps. 4. What are the causes of hemorrhage before and after delivery? 5. (a) What conditions necessitate version; (b) forceps delivery; (c) Cesarean section? 6. Describe a cesarean section. 7. Vaginal examination shows the saggital suture occupying the right oblique diameter; the small fontanelle is felt opposite the right sacro-illiac synchondrosis, the large fontanelle being directed toward the left and front. (a) What is the position of the child; (b) how may the case end; (c) treat the case if nature's efforts are unsuccessful. 8. What changes occur in the fetal circulation at birth. 9. Give the etiology and treatment of subinvolution of the uterus. 10. What is the cause and treatment of frequent urination in pregnant women?

### GYNECOLOGY

1. Name the different malignant neoplasms of the ovary. 2. (a) What symptoms and signs would lead you to suspect carcinoma of the body of the uterus? (b) Why is carcinoma of the body of the uterus less malignant than carcinoma of the cervix? 3. Name the muscles of the female perineum which may be torn during labor. 4. Describe the pathology of cystocele and of rectocele. 5. Name the causes of dysmenorrhea. 6. Differentiate between incomplete abortion and extra-uterine pregnancy. 7. Name the different varieties of uterine fibroids. 8. What general and local conditions may cause amenorrhea? 9. Describe the operative treatment for prolapse of the uterus. 10. What symptoms may follow retroversion of the uterus?

### HYGIENE

1. How does the expired air from persons differ in its composition from ordinary air? 2. Name at least six bacterial diseases in which the respiratory tract is the portal of entrance for the microorganism. 3. What are the advantages of pasteurized milk? 4. What is the specific gravity of normal cows' milk, and to what is it due? 5. What is understood by active and passive artificial immunity? 6. What is the value of temperatures and sunlight as physical disinfectants? 7. What is understood by an intermediary host in the transmission of infection, and give examples of diseases transmitted in this manner. 8. What measures must be instituted in the prevention of bubonic plague? 9. What is a diphtheria carrier, and what precautions should be observed with regard to the carrier and the community? 10. Which is preferable, the combined system of sewerage and drainage, or the separate system, and why?

## Nevada November Report

Dr. Simion L. Lee, secretary of the Nevada State Board of Medical Examiners, reports the written and practical examination held at Carson City, Nov. 3-5, 1913. The number of subjects examined in was 14; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 10, of whom 7 passed and 3 failed. Twelve candidates were licensed through reciprocity. The following colleges were represented:

# Book Notices

GONORRHEA IN WOMEN. Its Pathology, Symptomatology, Diagnosis and Treatment; Together with a Review of the Rare Varieties of the Disease Which Occur in Men, Women and Children. By Charles C. Norris, M.D., Instructor in Gynecology, University of Pennsylvania. With an introduction by John G. Clark, M.D., Professor of Gynecology, University of Pennsylvania. Cloth. Price, $6 net. Pp. 521, with 40 illustrations. Philadelphia: W. B. Saunders Company, 1913.

This is the most important treatise on the subject of gonorrhea thus far prepared in the English language. The work is most elaborate in its wealth of detail and is far more than a mere monograph. While dealing chiefly with the Neisserian infection in women the scope is necessarily broader. Thus in the chapter devoted to prophylaxis, the various methods employed to prevent infection in men is set forth at length.

After an interesting and comprehensive historical account the bacteriology of the gonococcus and the pathologic changes produced in the female genital tract are described. There is an unusually full description of the pus-tube, with several excellent illustrations. Chapters on sociology and prostitution are properly placed side by side and again indicate the breadth of the author's point of view. His statistical reports are most interesting. It is stated that of half a million prostitutes in our great cities, 40,000 die annually, 30 per cent., as a result of gonorrhea Approximately 60 per cent. of all gynecologic operations are performed for gonorrhea or its results. These chapters contain numerous and elaborate statistical tables. As a result of his exhaustive study of the subject of prostitution Norris advocates legal regulation, though recognizing the difficulty of securing efficiency. He is a strong advocate of instruction in sex hygiene for boys and girls of high-school age, believing that regulation is of minor importance as compared with educational methods in the ultimate solution of this difficult problem. Norris takes an advanced position again in his advocacy of an obligatory certificate of health for the male before marriage, and of a ruling making venereal diseases notifiable to the board of health. Indeed, he goes further and would make it a punishable offense to communicate a venereal disease.

In tracing the pathologic changes incident to this infection a topographic sequence has been adopted, beginning with the external genitalia and following the process through the vagina, uterus and appendages into the pelvis. The unusual manifestations and the remote complications are discussed in order as well as the relations of gonorrhea to pregnancy, labor and the puerperium. Gonorrhea in the extremes of life and its extragenital manifestations are clearly discussed. The operative methods of treatment are described comprehensively, emphasis being placed, however, on the importance of conservative medical treatment before surgical intervention is undertaken. In his operative procedures the author is a stanch advocate of conservative work, especially in the young woman. The cure by surgery of chronic gonorrheal processes involving the internal genitalia is essentially a mutilation, and whenever possible the function of menstruation should be preserved, as well as that of reproduction. The medicinal treatment of gonorrhea is exhaustively considered in the final chapter. The author's summary of what he considers the proper therapeutic care of the patient is of chief interest here. Foot-notes provide a vast amount of material for consultation. Far more than a text merely for perusal by the specialist or general practitioner, this volume in its breadth and comprehensive scope, as Dr. Clark well says in the introduction, may be accepted by the legislator and the sociologist as a fundamental treatise.

The Difficulties and Emergencies of Obstetric Practice. By Comyns Berkeley. M.A., M.D., B.C., Obstetric and Gynecologic Surgeon to the Middlesex Hospital, and Victor Bonney, M.S., M.D., B.Sc., Assistant and Gynecologic Surgeon to the Middlesex Hospital. Cloth. Price, $7.50. Pp. 787, with 287 illustrations. Philadelphia: P. Blakiston's Son & Co.

The object of this work, as frankly set forth by its authors, is to afford practical guidance to the practitioner when he is called on to deal with the difficulties and emergencies that attend obstetric practice. The more fundamental topics, such as the physiology and the management of normal pregnancy, labor and the puerperium, are omitted, so that the volume has rather the appearance of an operative obstetrics, differing only in that its field is broader, since it takes in all the pathology of labor, even the non-surgical complications. Thus a number of the early chapters are given over to complications of labor, such as disorders of the intestinal and urinary tracts, the gall-bladder, peritoneum and spleen, the nervous system, respiratory tract, and the heart and blood. In appendicitis the author favors operation on diagnosis. Again, in gall-stones operative interference is advised except during the last two months of pregnancy. On the other hand, in pyelonephritis conservative measures are to be adopted, operation being the rule only when the disease is bilateral. After termination, if the condition remains unimproved for one week, nephrotomy or nephrectomy will probably be indicated. Operation for hyperthyroidism should never be performed without first concluding the pregnancy. In valvular heart lesions, doubt is expressed as to whether the inevitable heart failure appears sooner in the majority of women who have borne children than in those who have remained sterile. Nevertheless, if compensation fails before the sixth month, pregnancy must be terminated, and in labor the second stage is always to be shortened artificially. Induction of abortion or premature labor in pulmonary tuberculosis is to be reserved for special cases, and the mother on no account is to nurse the baby.

In like manner the authors have advanced the more recent ideas in respect to the management of abdominopelvic tumors in connection with child-bearing and of uterine displacements with gestation. When there is evidence of retained fetal products in septic abortion, the uterus is to be cleaned out at the earliest opportunity. The tampon is the most preferred method in the treatment of accidental hemorrhage. Version and the rubber bag are favored in placenta praevia. Cesarean section is reserved for only the most favorable cases, and those in which the implantation over the cervical canal is complete.

Labor complicated by anomalies of the forces, of the genital passages and of the pelvis, and by malpresentation of the child, or by abnormalities of the child and umbilical cord, and labor complicated by rupture of the genital canal comprise a series of interesting chapters as conditions which invariably lead to operative interference. Fever in the puerperium is considered at length and from all its various aspects. Separate chapters are devoted to such topics as the breast, ectopic gestation, and anesthesia and analgesia during the labor. Obstetric operations are gone into in every detail and are profusely illustrated. Aside from a few minor technical differences, such as delivery with forceps in the lateral position, these procedures are identical in performance with those familiar in American practice. A long chapter on diseases and injuries of the new-born and a briefer one devoted to infant feeding conclude the volume.

At no time have the authors striven for brevity. The material fills a large volume and yet conciseness is evident on every page. Throughout, their views are well formulated, either in parallel columns or in one, two, three order. This, indeed, is the feature of the work. As an example, the conditions and indications for forceps extraction may be cited, or the treatment of eclampsia. Thus, while detail is abundant, verbosity is absent, and the volume gives rather the impression of completeness and extreme care in preparation.

An Elementary Study of the Brain. Based on Dissection of the Brain of Sheep. By Eben W. Fiske, A.M., M.D. Cloth. Price, $1.25 net. Pp. 133, with 19 illustrations. New York: Macmillan Company. 1913.

The preparation of an elementary text-book of neurology for premedical and other college students who have neither the biologic training nor the time for the mastery of the larger manuals adapted for advanced medical students is a peculiarly difficult task. The subject is intrinsically complex and difficult, and it is rendered still more so by a confused and cumbersome terminology and often by the failure of writers and teachers to clothe the anatomic detail with functional or any other meaning. Much of that which goes under the name of neurology in our schools is a meaningless jargon of no present or future value to the student. There is a real demand for a brief and very elementary introduction to the nervous system adapted for college students in zoology, physiology and psychology, and several small books of this character have recently been published, none of which, however, is very satisfactory. Beginning students in this subject are usually at first lost in the bewildering complexity of meaningless anatomic detail, and fortunate indeed are those who find their way through these mazes to a point at which they can see the plan of the whole structure. This can be facilitated only by limiting the content of such an introduction to the most important fundamental facts and by presenting no anatomic details whose functional significance is not at once made clear. The choice of these details and the plan of presentation, moreover, must be made by a master of the entire field with a true sense of proportion of part with part and with a unifying motive always kept in mind. The laboratory student is apt to perform his manipulations, faithfully following the directions, but without giving thought to the meaning of the exercise until it is finished—if even then. A beautifully finished dissection made in this spirit has little more pedagogic value to the student than the exercise of carving an effigy on a pipe bowl. The teacher's problem is to induce the student to keep his mind intent on the meaning of the work with which his hands are engaged, and it must be admitted that he derives but little aid in this from most of our manuals of dissection.

Dr. Fiske's little book is in some respects admirably planned. It presents an account of the gross anatomy of the brain of the sheep, with laboratory directions for its study, together with discussions of phylogeny, embryology and functions. These matters are not very well coordinated, however, and the student will probably fail to carry away any but hazy notions of the actual working of the nervous system from the work as a whole. The physiologic and other explanatory data appended to the anatomic sections are not always happily phrased, and the work is far from presenting (even when all dissections are made as directed) a clear picture of the brain as a functioning organ. The descriptive part, moreover, is marred by many erroneous statements. The chapters are illustrated by photographs of lower vertebrate brains taken from the Ziegler models, by a few simple sketches of embryologic stages of the human brain, and by a series of photographs of surface views, dissections and cross-sections of the brain of the sheep. The latter are worthy of the highest praise and, with the accompanying simple key drawings, will prove very useful.

PRACTICAL BACTERIOLOGY, MICROBIOLOGY AND SERUM THERAPY (MEDICAL AND VETERINARY). Text-Book for Laboratory Use. By Dr. A. Besson. Translated and Adapted from Fifth French Edition by H. J. Hutchins, D.S.O., M.A., M.R.C.S., Heath Professor of Comparative Pathology and Bacteriology of University of Durham. Cloth. Price, $10.50 net. Pp. 892, with 416 illustrations. New York: Longmans, Green & Co., 1913.

This work has been designed purely as a laboratory guide, the one object constantly in view in its preparation having been to make it a book which would both direct the beginner step by step and, at the same time, afford to the more skilled worker such assistance as would enable him to pursue his researches in a profitable direction. It is one of the most complete and satisfactory laboratory guides to microbiology with which we are acquainted. The value to all types of students is much enhanced by the avoidance of purely theoretical discussions. The subject-matter is arranged in seven parts as follows: general technic, the pathogenic bacteria, the parasitic fungi, the pathogenic spirochetes, the protozoan parasites, the filterable viruses, and the application of bacteriologic methods to the examination of water, sewage and air. Each of these sections is subdivided into many groups, so that the mass of information given is enormous. Each bacterial species is minutely discussed, the morphology, biologic properties, detection and isolation of the organism and the technic and results of animal inoculation being carefully and fully outlined. The illustrations, both plain and colored, are excellent.

MASSAGE. Manual Treatment, Remedial Movements. History, Mode of Application and Effects; Indications and Contra-Indications. By Douglas Graham, M.D. With Chapter on Massage of the Eye, by Dr. A. Darier. Fourth Edition. Cloth. Price, $5 net. Pp. 574, with 75 illustrations. Philadelphia: J. B. Lippincott Company, 1913.

This is a comprehensive, scientific work of a man who has devoted his life to the subject, and who has his own ideas and knows how to express them. His knowledge of French, German and Italian has enabled him to review a great deal of the literature on massage. What particularly makes the book readable is the fact that Graham always has an eye open for the humorous, and the fact that his humor sometimes is turned into sharp satire does not make it less easy to read. Particularly good are the sections on the history of massage, on the mode of operation and on traumatic joint affections.

HANDBOOK OF PHYSIOLOGY. By W. D. Halliburton, M.D., LL.D., F.R.C.P., Professor of Physiology, King's College, London. Eleventh Edition (Being the Twenty-Fourth Edition of Kirkes' Physiology). Cloth. Price, $3 net. Pp. 923, with nearly 600 illustrations. Philadelphia: P. Blakiston's Son & Co., 1913.

The present edition of this hand-book differs from the preceding one because several chapters have been rewritten and the others revised. The last two chapters of the previous edition are replaced by a new one on reproduction, development, growth and death. Heredity and eugenics are also briefly discussed. The work of revision, together with the introduction of considerable new matter, has been conducted in such a manner that the size of the book instead of being increased is actually less by a page than the previous edition.

## Defective Prosecution on Quarantine Order—Powers Under Statutes to Protect Public Health—Judicial Notice of Scarlatina

*(State vs. Rackowski (Conn.), 86 Atl. R. 606)*

The Supreme Court of Errors of Connecticut reverses for error a judgment of conviction, and orders a new trial for the defendant, who was charged with having violated an order of the health officer of the borough of Naugatuck quarantining her and her two minor children as persons whom the health officer had reasonable grounds for believing to be infected with scarlatina or scarlet fever.

The court says that the information assumed to charge the crime provided for by Section 2552 of the General Statutes of Connecticut, for a violation of an order of the health officer made under Section 2549, reading "Any town, city, or borough health officer or the board of health of a city or borough, may order any person whom they have reasonable grounds to believe to be infected with any malignant, infectious or contagious disease, into confinement in a place to be designated by them, there to remain so long as said health officer or board shall judge necessary." Before a lawful order can be made under this statute, the health officer must have a reasonable belief that the person or persons ordered into confinement are infected with a contagious disease.

The proof failed to meet the charge inasmuch as the information charged a violation of an order quarantining the accused because the health officer had reasonable grounds to believe that she was infected with a contagious disease, whereas the record did not show that the accused was either infected with that disease or that the health officer had reasonable grounds to believe she was so infected. There was therefore no basis for the charge that, if the jury found that the accused herself broke the quarantine by going abroad, it was their duty to find her guilty.

The state pointed out, with emphasis, the danger to the community if one having been exposed to a contagious disease might not be quarantined by the health authorities. Lest such a want of power may be inferred from this decision, the court points out the source of power of the health officer to prevent the spread of contagious diseases by an order quarantining those who may have been exposed.

This information did not charge the accused with violation of an order of confinement for having been exposed to a contagious disease. The statute on which it is based does not provide for or contemplate such an order. But that statute is only one of a body of laws designed to protect and preserve the public health. Such an object is a chief end of government, and the legitimate exercise of the power of the state for the accomplishment of such a purpose is a governmental duty which falls within the police power. Its origin rests in necessity. The prevention of the spread of disease is required either by express statutory provision or by the necessary implication arising out of the imposition of such a duty.

The Connecticut statute, Section 2531, as amended in 1905, invested the health officer of the borough of Naugatuck in common with the health officer of every city and borough of the state with "all powers necessary and proper for preserving the public health and preventing the spread of diseases therein." Statutes whose object is the protection and preservation of the public health should receive a liberal construction. The powers conferred by Section 2549, to prevent the spread of contagious diseases, are not exclusive, and do not limit the power conferred by Section 2531, as amended, over the spread of contagious diseases to orders relating wholly to the person who has the disease or whom the health officer has reasonable grounds to believe to be infected with such disease. The power to make all reasonable health regulations, including the quarantine of those who may have been exposed to contagious disease, is within the fair intendment of the powers conferred by Section 2531, as amended. The violation of such an order or regulation would be within the penalty of Section 2552.

The health officers of the state are not only bound to make all necessary and proper regulations to prevent the spread of disease, but they are bound to exercise the highest diligence in enforcing these regulations. Common knowledge tells us that contagious diseases may be communicated by those who have been exposed to the diseases. And it is the common practice for the health authorities to detain all such persons from going abroad so long as the danger of contagion is imminent from those who have been exposed.

The court affirms the legality of reasonable quarantine regulations by the Naugatuck borough health officers, designed to prevent persons infected with a contagious disease, or suspected by the health officer, on reasonable grounds, of either infection or exposure, from intercourse with other persons in the community. But the prosecution for violation of the regulations must be based on the order made.

As no complaint was made of this order on the ground that no period of confinement was specified, the court assumes that the period intended by the order was the duration of the danger from the disease to be determined by the health officer. Such an order was a reasonable quarantine regulation.

A mother who directly violates a lawful order of a health board, whether made under Section 2549 or not, or who knowingly permits her child for whose custody she has legally been made responsible to violate that order, is equally guilty of the offense whose penalty is prescribed by Section 2552. The jury might under the facts before them have found the existence of such an order.

One instruction to the jury gave rise to the question whether there exists an experience or probability so general as to have resulted in a presumption of universal acceptance, in the absence of proof to the contrary, that when a child is abroad in violation of a quarantine order this is with the mother's knowledge and consent, or whether there is any policy or convenience of the law which has compelled the acceptance of such a presumption. The court thinks that there is no policy of the law to rest this presumption on, and that experience proves the reverse of this assumption. A mother's love for and care of her sick child is the general presumption of all people, of all times, and of every social rank. There is no presumption of law that the mother knew and consented to the violation of the quarantine order, and hence the trial court erred in charging that the state made out a prima facie case against the mother by mere proof of the violation of the order by the children. Whether any inference was to be made of the mother's knowledge and consent to the violation of the quarantine order from the circumstances of this case was an inference of fact within the province of the jury. An inference which may or may not be drawn by the jury is far different from a presumption of law which must be drawn until proof to the contrary is offered.

The court was clearly right in taking judicial notice that scarlatina is an infectious or contagious disease.

### City without Right to Pollute River with Sewage

*(Attorney-General vs. City of Grand Rapids (Mich.), 141 N. W. R. 890)*

The Supreme Court of Michigan says that this was a proceeding to declare and to abate and restrain the continuance of an alleged public nuisance which was claimed to result from acts of the city in conveying through artificial means its sewage into the Grand River, which flowed down the river and was cast on the lands below that city, and particularly on those lands which are adjacent to and within the village of Grandville. In the court's opinion the equities of the case were with the complainants, and the testimony made out a case of public nuisance. If the city in emptying its sewage into Grand River, as shown by the evidence, created a nuisance to the public or riparian proprietors below the city, the continuance or creation of that nuisance might properly be restrained by injunction, and the attorney-general was a proper complainant.

Undoubtedly the city has the right to make a reasonable use of the waters of the river as a riparian owner. But the court's attention has not been called to any statute giving the city the right to use Grand River below its limits as a sewer for the purpose of carrying away its waste and refuse in an unreasonable manner; and, if it were attempted by statute to give such a right, the statute would be unconstitutional, unless it first provided that the owners of property along the river should be compensated for damages to be first determined by constitutional methods for destruction of such property rights. If the city creates, or threatens to create, a public nuisance, particularly outside of its corporate limits, it is subject to the same rules as would be a private individual, particularly when in the creating of such nuisance it acts not in a governmental but in a private capacity.

There can be no prescriptive right, that is from long usage, to pollute a stream by the discharge of sewage in such a manner and to such an extent as to be injurious to the public health. Even assuming that a prescriptive right to foul a stream with sewage can be acquired, such must be restricted to the limits of it when the period of prescription commenced; and if the pollution be substantially increased, whether gradually or suddenly, the court will interfere by injunction to prevent the wrongful excess; and, if it be impossible to separate the illegal excess from the legal user, the wrongdoer must bear the consequences of any restrictions necessary to prevent the excess, even if it unavoidably extends to the total prohibition of the user.

No person is entitled on the ground of ancient custom to the privilege to collect a mass of sewage matter and pour it at one point into a stream in such a quantity that the river cannot dilute it on its passage down to the lower riparian proprietors, as the effect of such an act is to create an evil which must be illegal, being such as no custom can authorize. The general rule is that sewage cannot be cast into the stream to such an extent as to pollute it. Sewage cannot be thrown into the stream in such a way as to render the water foul and unfit for use.

Wherefore the decree of the court below in favor of the defendants is reversed, and one entered for the complainants restraining the city, its boards, officials, servants and agents from continuing to discharge the sewage of the city into the Grand River, until the same shall have first been, by the use of a septic tank or tanks, so deodorized and purified as not to contain the foul, offensive or noxious matter (which it now contains) capable of injuring the complainants or their property, or causing a nuisance thereto; such injunction to become operative one year after the date of the settling of decree. The complainants will also recover of the defendant city their costs of both courts.

### Physician's Liability—Presumptions Do Not Relate Backward

*(Adams vs. Junger (Iowa), 139 N. W. R. 1096)*

The Supreme Court of Iowa reverses for trial errors a judgment for alleged malpractice in the treatment of fracture of the neck of the femur of the plaintiff's left leg, sustained January 11. The defendant was immediately called, and arrived at the plaintiff's house within an hour and a half of the time she received her injuries. He continued to treat the case until May 29. On June 5 the plaintiff's husband called on the defendant and paid his bill, making no complaint. A roentgenoscopy, made June 24, disclosed the fact that the fracture had not been reduced, that there was a non-union of the broken bones, and that one end of the bone had extended up into the flesh for an inch or more, causing excruciating pain; but there was no testimony of any negligence on the part of the defendant in his original treatment, or in the use of the appliances which he did in fact use.

There was error in the instructions given to the jury. If the court had in mind the thought that the defendant did not, in discharging the plaintiff, properly direct her as to the care of the limb, or that he did not then examine her for misplaced bones, he should have instructed the jury that it could not allow for any pain or suffering occurring prior to the time that the defendant was found to be negligent. In other words, if, as the court instructed, the defendant was not negligent in his original treatment, he *could not* be held for any suffering endured by the plaintiff during the time this treatment continued, and, if held responsible for something occurring after this treatment ceased, he should be held liable only for such pain and suffering, if any, as resulted from his negligence at that time, and not for what might have been endured from the beginning. And, in any event, the plaintiff could not recover, unless she proved the negligence charged in her petition, and her damages must be limited to such as proximately arose from the negligence charged.

Presumptions do not ordinarily relate backward. A condition, once shown, may be presumed to continue; but ordinarily from a condition once found no presumption is indulged that it has existed for any given time in the past. True, such presumptions sometimes arise in virtue of the nature of the condition; but this arises from proof of other things in addition to present conditions, as its condition of permanency of progressiveness.

### Liability of Agent of Corporation for Unlawfully Practicing Medicine

*(Norwood vs. State (Texas), 158 S. W. R. 270)*

The Court of Criminal Appeals of Texas says that the main contention in the court below of the appellant (defendant), who was convicted for unlawfully practicing medicine, was, in effect, that, while numerous patients were treated in the hospital of which he had charge, it belonged to a corporation, and he was the mere manager, employee and agent of the corporation in whatever was done in the way of treating patients, receiving pay therefor, etc. The court at his instance gave this special charge to the jury: "You are instructed that if you believe from the evidence that the treatment given to Vinnie Spangler was given by the Norwood Institute, a corporation, and not by the defendant, then, in that event, your verdict should be for the defendant, and you should say by your verdict not guilty." This special charge was not the law and should not have been given. Even if he was an officer, agent, servant or employee of said corporation and committed the offense charged, even though purporting to act or acting for the corporation, he would be guilty. Mr. Bishop in his Criminal Law, in Section 892, says, "An agent or servant who, knowing the facts, does a criminal thing for his principal or master, is answerable to the criminal law precisely as though he had proceeded self-moved, and for his own personal benefit. And it is the same when with the like knowledge he merely assists therein." Again, in Section 685, he says, "The authorities agree that there are in misdemeanor no accessories either in name or in the order of the prosecution." Mr. Branch in his Texas Criminal Law, Section 681, lays down this rule: "There is no distinction between principals and accomplices in misdemeanors; a party who would be an accomplice if the offense was a felony is a principal if the offense is a misdemeanor. If defendant comes either within the definition of an accomplice or a principal, he is a principal in a misdemeanor." Then there was a fatal variance between the allegations and the proof in this case in that the allegations charged that the defendant did unlawfully treat a disease or disorder, to wit, did treat Vinnie Spangler for consumption, diagnosing her case and prescribing some gas treatment therefor, while the proof did not establish or tend to establish that Vinnie Spangler had consumption or was treated for consumption.

**Small-Pox.**—Eleven of the thirteen patients now in the small-pox hospital of Chicago, qualifying for waffle-iron faces, came from a "health institute" which denounces vaccination as wicked, superstitious, useless, nasty, impertinent and an "invasion of personal rights." This condition is typical. Small-pox has been well named the "poisoned arrow of the fool-killer." Those who want to escape these arrows had better provide themselves with the only shield that experience has proved effective—vaccination.—Chicago *Journal*.

## CHICAGO-PEDIATRIC SOCIETY

*Regular Meeting, held Nov. 21, 1913*

The President, Dr. Frank X. Walls, in the Chair

### Report of Two Cases of Pachymeningitis Hemorrhagica

Dr. Grace Meigs: This condition has been well recognized in the adult for a long time, but only recently as not uncommon in children, especially in infants. The onset is characterized by convulsions, vomiting and signs of acute meningitis. In 1881 it was first suggested that the condition could be diagnosed during life. Finkelstein, in 1904, suggested that a puncture of the fontanel could be made in these cases, and a bloody fluid, characteristic of the disease, could be obtained. He also was the first to mention the presence of retinal hemorrhages.

The cause of pachymeningitis hemorrhagica has been variously explained. The older writers, in describing the condition in adults, ascribed it chiefly to tuberculosis and syphilis, but Huebner thinks that congenital syphilis is by far the most frequent cause; also chronic gastro-intestinal diseases. Finkelstein, however, thinks that rickets is the most important predisposing cause. Hahn suggests that it is a manifestation of the hemorrhagic diathesis. Virchow thinks that the primary lesion is an inflammation of the dura mater. All are agreed that it is apparently due to toxins.

The post-mortem findings are characteristic. The inner surface of the dura is covered with a membrane, most abundant on the convexity, but usually present all over the dura. It is rather closely adherent, but can usually be peeled off from the dura, leaving it quite smooth and only somewhat thickened, with a few ecchymoses. The membrane varies in thickness from the most delicate cobweb-like membrane to a very thick connective-tissue layer. There are many layers, and between them the hemorrhage occurs, spreading them apart so as to form a bag, into which there is often an effusion of fluid, and then probably later hemorrhages; at least all stages are found with simply a yellow fluid or a fluid containing blood, or simply with blood-clots. The brain itself shows no changes, except evidence of pressure.

It is not known just what the effects of such a condition would be on the brain in after-life. It is possible that some of the paralyses of childhood may be due to this condition. The spinal fluid in all the cases reported contained some blood —very often only found microscopically; but sometimes the fluid was markedly hemorrhagic.

In some cases no clinical symptoms of any kind are shown during life, but the condition is found post mortem. In those which do show symptoms there are two classes: First, the symptoms are those of hydrocephalus with recurring attacks simulating an acute meningitis, with coma, convulsions, vomiting, strabismus, opisthotonos and all the other symptoms; secondly, the symptoms are merely those of hydrocephalus, together with perhaps increased reflexes or a little rigidity. In both classes there is evidence of a hydrocephalus —that is, the fontanel is large and bulging, the sutures are gaping, and there is often a hydrocephalic stare. This enlargement of the head is sometimes very sudden. The most characteristic findings are those of a choked disk and retinal hemorrhages, the latter being fairly diagnostic. Important for diagnosis, however, is the finding of fluid on puncture of the fontanel, and this procedure is quite without danger in all cases. The only thing to be avoided is puncture of the central sinus, which can easily be done by making the puncture at the lateral angle of the fontanel. A needle with a short point is used. In the positive cases, immediately on going through the skin and somewhat resistant dura there is a gush of fluid, under mild pressure. This fluid is quite characteristic, being composed of a bright yellow or orange serous layer, and a layer of dark, chocolate-colored erythrocytes. These show evidence of having been long in the fluid. The erythrocytes settle at the bottom when the fluid stands, and there is no coagulation.

In treatment, probably the most commonly used measure is lumbar puncture, and this is proved to have good effect because several patients who have been observed through the course of the disease and have died from some other diseases afterward have shown the trouble in the stage of resolution and cure. Finkelstein does not think that puncturing the fontanel does any permanent good. He advises the use of gelatin, and injects 20 c.c. of a 10 per cent. solution. Huebner uses the antisyphilitic treatment with the idea that most of the cases are syphilitic, and he has seen good effects.

My first case while not a definitely proved case, was very suggestive of this condition. The baby was 3 months old, and was admitted with the diagnosis of hydrocephalus. There was no syphilitic or tuberculous history. The condition of the head had been present since birth, but had lately been getting worse. Examination showed a well-developed child; the head was enlarged and the sutures separated; the eyes were turned to the right and fixed. A few days later the right arm was inverted and flexed, and not moved; later the left arm showed the same condition. For the first few days the condition was quite good, but about three days after entrance an acute attack began, with convulsions, lasting one and a half minutes, with twitching of the right side of the face. Temperature was 101 F. Stools were good at this time. Lumbar puncture showed fluid under a high pressure; there were 7,000 leukocytes to the cubic centimeter. Noguchi was positive. There was no evidence of syphilis. Reaction was positive for a condition of inflammation. The cultures and smears were unsatisfactory. An organism was seen which the pathologist considered a contamination. It looked rather like an influenza bacillus. A tentative diagnosis of pachymeningitis was made, and puncture of the fontanel on the left side done because the symptoms were so well localized on the right side. The fluid was obtained under quite mild pressure, was opalescent and with quite a mixture of blood, but was not yellow On standing, it coagulated and there was a marked deposit of blood. It was sterile. Spinal puncture made at the same time gave an opalescent fluid, with a slight precipitate of blood. It was seen only after having stood for twenty-four hours. The blood was evidently thoroughly mixed with the fluid. The leukocyte count was 100 per cent. No cell count was made, on account of the mixture with blood. After this the child's condition improved, but later it developed nasal diphtheria and died.

The second case was undoubtedly one that could not be diagnosed during life. There were no symptoms except enlargement of the head. The child was 4 months old, and was brought into the hospital, not on account of the condition of the head, but merely because of the failure to gain, vomiting and constipation. It had a history of gastro-intestinal disturbance. The child was small, emaciated and old-looking. The head was very large and the face small; the anterior fontanel was 4 fingers in diameter. The coronal suture was very wide: the other sutures were plainly palpable. The circumference of the head was 41.25 cm. The neck was not rigid. General examination was entirely negative, except for the emaciation and for the finding of an enlarged spleen and enlarged lymph-nodes. The urine was negative. The Wassermann reaction, both in blood and in spinal fluid, was negative. Lumbar puncture was performed and 20 c.c. of fluid obtained—quite clear and under considerable pressure. The remarkable thing in the course of this case was the decrease in the size of the head (from 41.25 cm. on entrance to 39 cm. at death), which began very soon after the lumbar puncture. While in the hospital there was gradual loss in weight, very bad stools, and finally, twenty-four days later, during very hot weather, the child died quite suddenly. The diagnosis was decomposition and internal hydrocephalus.

Post-mortem was made thirty-six hours after death, and an examination only of the head made, and the condition of pachymeningitis hemorrhagica shown. When the skull cap was taken off bloody fluid escaped, and we found that the inner surface of the dura was entirely covered with a membrane which was in some places quite delicate and thin, and in others thick. It could be peeled off the dura, but was rather firmly adherent in some places. The base of the brain was also covered with the same membrane. There were a great many different layers to be distinguished, and in one place, over the left anterior portion, underneath the puncture, there was about an ounce of bloody fluid. The brain itself was soft and the surface quite negative. There was a moderate degree of internal hydrocephalus present. Microscopically, the dura was thickened and this membrane showed all the different stages of granulation tissue and connective tissue. In some places numerous large blood-vessels were seen, and in other places ecchymoses.

### The Feeding of Five Hundred Infant-Welfare Babies

**Dr. R. A. Krost**: The work done at the conference now is exceedingly gratifying, the former distrust shown by mothers has disappeared, and they now follow our instructions quite faithfully in most cases. The gospel of regularity of feedings, the use of certified milk and the longer interval of feeding has spread, as evidenced by the number of new cases. Individual milk prescriptions calling for certified milk are given. They are prepared by the nurse at the baby's home until the mother can prepare them correctly. The feedings are made as simple as possible, using usually an ounce and a half of certified milk to the pound weight of the child. The milk is diluted with barley-water in varying amounts, according to the child's age, and to the diluent about 5 per cent. cane-sugar is added, although almost never is more than ¾ ounce used. I think that 2 ounces is nearer the amount necessary to bring about a 4-ounce gain or more per week with the small amount of sugar used. Cane sugar is used because it is cheaper. In cases of diarrhea the babies were put on saccharin-sweetened barley-water for from twenty-four to thirty-six hours; then diluted boiled skimmed milk was used, then diluted whole milk, and, lastly, sugar was added. Early in the work I fed the babies on the four-hour interval plan, and later changed it to three because of the inability to feed the ordinary healthy baby enough food to satisfy its caloric needs by the four-hour feeding without using too concentrated a food or too much sugar. Between feedings a few ounces of boiled water were given, if the infant cried.

A mistake too often made in the cases of malnutrition and marasmus is a frequent change in food. A baby becomes adapted to its food; therefore, it is unwise to change it. The weight may remain stationary for a time, or there may even be a slight loss, but eventually there is a gain. In addition to the milk, once a day we gave the babies aged 6 months or over, and sometimes even younger babies, broths containing crumbled toast or farina. Probably the addition to the cow's milk diet brought about its better digestion and assimilation.

I have used boiled milk for six months and found no bad effects from its use. Constipation is perhaps a little more frequent and persistent than on raw milk, but not much. There is little vomiting, less than on boiled milk, and less colic. The gains are about the same from week to week, but greater on boiled milk if followed for months.

There were twenty-eight deaths from all causes in 5,475 cases, a percentage of 5.8. In eighteen cases diarrhea or nutritional disturbance was the cause. These diarrhea deaths occurred during July, August and September.

#### DISCUSSION

**Dr. Albert H. Beifeld**: The most common causes of infant mortality are poverty, ignorance and neglect. Simple mixtures should always be used. One of the most important points is the training of the physician. He should learn that each component of breast-milk has a definite physiologic action in digestion and nutrition, and he should be able to manipulate each one of the components so that he will obtain a result without having to rely on the complicated mixtures, such as *Eiweissmilch*, buttermilk, malt soups, etc. There are certain faults which we are tending to fall into in this matter. One is that we do not give enough fat in the food, and another that we are inclined to a rather slavish adherence to the malt-dextrose preparation. Just as the mother should be trained to develop a certain sense of independence in caring for the baby and understanding how to control its feedings, so the baby's intestine should be trained to endure the more actively fermenting sugars, such as cane-sugar or milk-sugar, and if we persist slavishly in the use of malt-dextrose preparations we are pampering the baby's intestine. These things should be used as therapeutic measures, as intended by the inventor. I endorse the early addition of foods in the feeding of these bottle-fed babies. It has a striking effect, when we give a little portion of soup each day to the baby which has been fed solely on milk. I have seen several babies recently that have been brought from hospitals where they have been fed according to rule and regulation and the highest dictum of our scientific calling, and they were in a miserable condition because they had had nothing to eat.

One other point: We can get along very nicely without the use of *Eiweissmilch* by the administration of simple protein, the dried casein preparations. I recall two cases, with astonishingly striking results, in which, after three, four and five weeks of these slow losses in weight, the addition of a certain casein preparation brought about a gain in weight in two or three days. I think that we are inclined to be afraid of the amount of sugar used. It is neither a foreign body nor a poison. I think that just as we should use a sugar which will train the baby's intestine, we should use as liberal a supply as the condition demands. The outlook is very good in the home modification of milk. At first the mothers are a little bit slow, but when they see the results they become enthusiastic.

**Dr. H. F. Helmholz**: Dr. Krost thinks that very few cases of diarrhea are due to overfeeding. I should like to call attention to the large series of cases published by a pediatrician in Breslau, in which babies, given as low as 50 and 60 calories per kilogram of weight, gained very rapidly. On questioning the mothers closely it was found that they were giving the babies additional food. Even though we have these mothers very much under our control, still a great deal of food is given, frequently in excess of that which has been ordered.

**Dr. Frank X. Walls**: These results are particularly interesting, when we consider that only 3.8 per cent. of these babies die. It is in striking contrast to the figures in our text-books as to the death-rate among artificially fed babies. When we consider this low mortality at the conference, it would seem as if the death-rate mentioned comes in great part from the other large majority which are under the treatment of physicians who probably have not the training that the conference physicians have.

The question of weaning babies is an important one. I have found in private practice that great harm often comes from attempting to put a baby who has received only mother's milk for seven, eight or nine months, on other food. It will often refuse it for a week and become desperately ill.

**Dr. Joseph Brennemann**: We are perhaps apt to overlook the striking results obtained with such simple measures. That point should be emphasized. When we think of what the mortality ordinarily is, one is impressed with the fact that these results are striking. Practical infant-feeding cannot be learned in a hospital—it is an ordinary proposition. The vast majority of babies are fed in the home, and conditions in hospitals are entirely different. I am not saying anything against the work done in hospitals, but such a paper as this, giving such results, would certainly lead one to think that there is a good deal in the idea that babies ought to be fed at home as much as possible.

## The Use of Dextrose Solutions in Acute Intoxication in Infants

**Dr. H. F. Helmholz**: In such cases, because of a severe diarrhea, food must be administered by the subcutaneous or intravenous route. It has been customary to give simply a sodium chlorid solution, isotonic with the blood, or Ringer's solution. Recently Kausch called attention to the advantage of giving sugar solution instead of a saline solution. He used a 5 to 7 per cent. solution of dextrose, giving a liter either subcutaneously or intravenously. The sugar is not only well tolerated, but the worse the condition, the greater the sugar tolerance. In cases of cyclic vomiting, which are usually marked by an intense acidosis, saline-dextrose solutions by clysma by the drop method have given good results. It seems probable, therefore, that dextrose added to Ringer's solution should act beneficially in cases of acute gastro-intestinal intoxication marked by acidosis, extreme prostration, vomiting, diarrhea and collapse.

Our routine method of treatment is to withhold all food for from twelve to twenty-four hours, giving merely water or tea by mouth, and stimulating the failing circulation by the use of caffein, camphorated oil, brandy and saline solution subcutaneously. The demand for food is great. All of the infant's resources are being exhausted by the disease. The only route for placing food in the body is the subcutaneous or intravenous. In such cases dextrose is the ideal agent to use. It can be given subcutaneously, say 50 c.c. of a 50 per cent. solution, without harm. Almost 60 gm. have been given, with only a trace appearing in the urine. The most important thing to ascertain is whether the dextrose solution is indicated, whether it has any effect on the rapid loss of weight, and whether its presence in the tissues leads to edema. Finally, what are the effects on the clinical picture?

The solution is prepared as follows: To 1,000 c.c. of freshly distilled water add dextrose, 60 gm.; sodium chlorid, 7.5; sodium bicarbonate, 0.2; calcium chlorid, 0.2, and potassium chlorid, 0.2. Filter and sterilize in flasks of about 100 c.c. capacity. The solution is given hypodermically, either by gravity or by means of a large syringe, in doses of from 50 to 200 c.c. It is injected under the skin of the abdomen or under the pectoral muscles. The smaller doses at shorter intervals are preferable.

We have given the solution in about twenty cases, most of the patients being *in extremis*. In not a single instance was sugar found in the urine. Unfortunately, the stools were not examined for sugar, although it is probable that only very small amounts of sugar left the body through that tract. It would appear, therefore, that the infant in a state of intoxication can tolerate from 4 to 6 gm. of sugar two or three times a day and completely utilize it. Whether or not concentrated solutions can be given with greater benefit is unknown. A study of the weight-charts shows that the water is retained better with the sugar than without it, so that the sugar solution is preferable to the salt solution. In several instances in which the toxemia was intense the loss of weight was comparatively slight, and at no time during the injection was there any palpable edema to explain the maintenance of weight. In some instances the weight was greater at the time of death than on admission. In only exceptional cases were the losses in weight such as one is accustomed to see in these cases. In some cases of intoxication there is apparently no effect from the use of sugar solution. In the majority of cases, however, there was quite a definite improvement (1) in the tendency to come out of the coma; (2) in the improvement of the turgor, and (3) in the circulation. In one or two instances it seemed to be the only thing that kept the infant alive.

### DISCUSSION

**Dr. J. H. Hess**: Did you notice the effect of the administration of dextrose on the acetone in the urine? How long did you keep these babies on the dextrose, on the average?

**Dr. H. F. Helmholz**: Usually we kept them on water for from about twelve to twenty-four hours, and then started them either on very minute amounts of *Eiweissmilch* or breast-milk. The other routine was about as we have been accustomed to doing. We kept up the use of dextrose solutions for longer periods after we started other foods, but otherwise the feeding was carried on just about as usual. We could not obtain any urine until after giving the solution—and in one case it was twenty-four hours after.

Dr. Albert H. Beifeld: Did you find albumin in almost every case? It has seemed to me that an irritated kidney sometimes holds back the salt and sugar, just as we hear of a diabetes being controlled by a nephritis. If you had a nephritis in every case it might explain the absence of sugar in the urine.

Dr. H. F. Helmholz: After we got further along, we obtained specimens of urine in which there was no albumin, but, as Dr. Beifeld undoubtedly knows, it is usually most severe. We found casts and albumin, but they did not seem to have any related function, nor did the retention of sugar seem to have any relation to the irritation of the kidney from the other cause.

9. **Value of Wassermann Reaction.**—Post suggests that the Wassermann reaction should be regarded as a symptom like other symptoms, and in relation to other symptoms, it will prove a wonderful help. To insist on calling it a test, confuses rather than aids.

10. **Comparative Psychology in Relation to Medicine.**—Yerkes says there are no aspects of organic reaction which are not worthy of accurate measurements in a psychologic investigation. The reflexive and the instinctive often prove to be quite as important as the impulse or voluntary. Comparative psychology deals with facts and principles which are of extreme importance to the physician; it deals with these facts in a systematic, quantitative, law-evoking manner which renders it immediately serviceable to medicine.

The situation in Yerkes' opinion is this: A science of conscious behavior, introspective and quantitatively observational, comparative and rigorous in its demands for verifiability, is developing. Will those who are interested in medical education make use of it or will they continue to permit students to grapple with the problems of human nature without systematic training in the methods of studying conscious behavior, and without a good working knowledge of the facts and principles of human behavior? It is a case of "heads I win, tails you lose," for comparative psychology has much to give and medicine much to gain, and whether or not students of medicine avail themselves of its assistance, it will progress steadily, little by little supplying the principles of organic nature which should enter into the foundations of our social sciences and guide in the varied applications of natural science.

11. **Problems of the Adolescent.**—During the last eight months Lucas examined 123 patients between the ages of 10 and 20 years; 71 per cent., or 88, of these showed some evidence that adolescence had some relation to the condition for which they were brought in. The reasons for bringing these cases in was mainly mental examination. Physical examination brought out the fact that over 39 per cent. of these individuals were normal; under par, 30.89 per cent.; nervous, 24.39 per cent.; those having speech defects, 12.19 per cent.; eye, 9.75 per cent.; ear, 4 per cent.; epilepsy, 5 per cent., and enuresis, 4.87 per cent.; also those having had previous convulsions, 6.5. Naturally, the greatest disturbance was in their volitional powers; a very large percentage being defective or retarded (57.7 per cent.).

12. See The Journal, Nov. 1, p. 1628.

13. **Bacterial Vaccines in Acute Septic Conditions of Mouth.**—Medalia attempts to show by a citation of cases that vaccine treatment is of value in acute septic dento-alveolar abscesses—even the worst types of mandibular impacted third molar abscesses having apparently yielded well to this treatment. Such cases with septic apical abscesses, especially the deep-seated ones or the so-called blind abscesses, acute and subacute, have been greatly benefited by the vaccine method of treatment. Medalia believes that there is a big field for vaccine treatment in acute and subacute dento-alveolar abscess cases and its wide-spread use will save considerable suffering and loss of teeth to the patient, and annoyance to the dentist.

14. Abstracted in The Journal, December 6, p. 2100.

15. **Nitrogenous Waste Products in Blood in Chronic Interstitial Nephritis.**—The effect of high and of low proteid diet on patients suffering from chronic interstitial nephritis, with increased arterial tension was studied by Seymour. Fourteen patients were selected, each case having an arterial hypertension, persistent low gravity urine, with small amounts of albumen, and rare hyaline casts. For five days the patients were given the regular hospital diet, which contained about 60 grams of proteid. At the end of this period the proteid content of the diet was increased and this diet maintained for seven days. By the sixth day they were given about 180 grams of proteid daily. During the next period of eight days, the proteid was reduced, so that they were given very small amounts, the daily average for this period being about 12 grams.

The nitrogen content of the blood was measured at the end of the normal hospital diet period, and at the end of the high and of the low proteid diet periods. Urinary nitrogen determinations were made daily, except on the days when the phenolsulphonephthalein tests were made. These latter were made five times during the course of the experiment. Out of the fourteen cases, eight showed an increase in the nitrogen content of the blood at the end of the high proteid period. Of these eight cases showing a nitrogen increase, six had edema of the face with puffiness of the eye-lids, and complained of nausea and headache. All of these patients vomited, and in each case refused food at the end of the sixth day. Two of the patients who showed the greatest increase in the blood nitrogen, had more marked symptoms than those showing a more moderate one. Two cases showing an increase in the nitrogen, had no symptoms.

Of the six patients showing no increase in the nitrogen of the blood, one had only edema of the face, two had nausea and vomiting with slight edema of the face, two were drowsy, dull, and complained of headache. One patient showing no nitrogen increase, had no symptoms. Two showed a simple irregularity, three no change, and one patient showed a lowering in the blood-pressure. There seemed to be no relation between the arterial tension and the low proteid diet during the eight-day period the diet continued. In some cases there was an irregularity, in some a rise, and in others a fall in the pressure; even though the nitrogen content of the blood was greatly diminished in every instance.

17 *Experimental and Clinical Study of Value of Phenoltetrachlorphthalein as Test for Hepatic Function. L. G. Rowntree, S. H. Hurwitz and A. L. Bloomfield, Baltimore.
18 *Tests for Hepatic Function and Disease under Experimental Conditions. G. H. Whipple, T. C. Peightal and A. H. Clark, Baltimore.
19 *Test for Hepatic Injury: Blood Lipase. G. H. Whipple, Baltimore.

17. **Value of Phenoltetrachlorphthalein as Test for Hepatic Function.**—However, the constant findings in health, the decreased output in liver disease, the analogy between the effect of anemia and myocardial insufficiency on kidney and liver function as indicated by the sulphonephthalein and the tetrachlorphthalein tests, the results of the test in experimental liver lesions, and the established value of sulphonephthalein, based on the same principle as the test in kidney diseases, the authors believe, all indicate that the excretion of tetrachlorphthalein will be useful in the estimation of the functional capacity of the liver.

18. **Test for Hepatic Function.**—This test, the authors believe, promises much in the study of derangements of the hepatic parenchyma, physiologic and anatomic. Its great value is that it may give some quantitative values concerning liver injury, and for this reason, with accumulated experience, may be of value to the clinician.

19. **Test for Hepatic Injury.**—A study of the lipase of the blood, Whipple says, will show a definite rise above normal in practically all cases of eclampsia, liver injury with necrosis due to poisons, intoxications or infections, acute yellow atrophy, cholangitis and abscess of liver with considerable destruction of liver tissue. Cirrhosis of the liver may show a subnormal lipase; it may react to liver injury by a rise in blood lipase, but this point will require more study.

24. **Tumors Proper and Hyperblastosis.**—Whatever be the essential cause of the autonomous blastomas, Adami states, we have in these hyperblastoses a group of diffuse overgrowths which by analogy must be regarded as due to disturbances of metabolic equilibrium; which, further, in their simple nonmalignant stages at least, may possibly be combated eventually (certainly not to-day) along the lines of organotherapy. Every transition is observable in this series between the development of overgrowths of fully differentiated tissue, nonmalignant grades of anaplasia, and diffuse malignant infiltrative growths. This suggests strongly that the causation of malignancy is not to be sought for in the entry and action of external agencies, but in stimulation of the growth properties of specific tissues by changes in what Adami terms tissue equilibrium. The more we study, the more we become impressed by the fact that the number of conditions of hyperblastosis, whether simple or malignant, is relatively considerable, so considerable as to deserve separate consideration.

34. **Production in Monkeys of Antibodies for Human Corpuscles.**—In the course of certain experiments on measles and other diseases in the monkey the opportunity was used by Hektoen to follow the development in the monkey of antibodies to human blood-corpuscles. His observations were made on five monkeys (*Macacus rhesus*) injected with human blood. The forms of antibody action detected were agglutination and, in one case, opsonification. The agglutinative mixtures were in quantity 0.6 c.c.; of this, 0.2 c.c. was a 5 per cent. suspension of washed human corpuscles, the rest, monkey serum and salt solution. The opsonic mixtures were made in the same way with the addition of washed monkey leukocytes obtained from exudates produced by the injection of suspensions of aleuronat into the pleural cavity, the total quantity here also being 0.6 c.c. The smears were made after an incubation of 37 C. for one hour.

There was no phagocytosis in similar mixtures in which human leukocytes were substituted for leukocytes from the monkey. The heated serum of these monkeys in quantities of 0.2 c.c., complemented either with fresh monkey serum or with guinea-pig serum (0.0125 c.c.), did not cause any lysis of human corpuscles (0.2 c.c. of a 5 per cent. suspension). No tests for precipitin were made.

The results of these observations as interpreted by Hektoen indicate that in the monkey, injections of human blood stimulate the formation of agglutinin and opsonin for human corpuscles, these antibodies describing the same sort of a curve, though of small range, as other antibodies after the injection of a single dose of antigen. If we may judge from just one or two instances, the injection of monkeys with comparatively small quantities of human blood gives a larger response than injections of large quantities. Hektoen suggests that the fact that monkeys respond in this way to human blood might be taken advantage of in differentiating between human and monkey blood, but self-evidently this would be possible only under very special conditions, so that the method would seem to have an extremely limited practical significance.

35. **Methylene Blue in Tuberculosis.**—It was found by DeWitt that methylene blue will penetrate the tubercle, stain the living tubercle bacillus, and in some cases kill the bacillus *in vitro* and in others lessen its virulence. When added to the culture media, a relatively small percentage of methylene blue will inhibit the growth of the human tubercle bacillus. DeWitt says that methylene-blue iodid is no less irritant than the chlorid and has less bactericidal power and no

greater therapeutic value. The new methylene blues used are various modifications of the methylene blue molecule and have in the main no advantage over methylene blue. New methylene blue GG, however, showed some effect in the one case in which it was used therapeutically and it, with other oxygen derivatives of methylene blue, will be given further tests.

Selenium blue and tellurium blue are new blue dyes in which the sulphur of the methylene blue molecule is replaced by selenium and by tellurium. They are weaker and less stable dyes than methylene blue and more toxic and less bactericidal than that dye. They penetrate the tubercle and are reduced in it and can be reoxidized; they stain the living tubercle bacillus, but more faintly than does methylene blue. In fact, they behave in all respects as weaker editions of methylene blue and have no advantage over it. Neither methylene blue nor any of the allied dyes tested by DeWitt had much therapeutic influence over experimental tuberculosis of the guinea-pig. While methylene blue seems for many reasons a favorable starting-point for tuberculosis chemotherapy, the author says that other modifications of it and probably many others must be tried before we can claim to have found a specific for this disease.

36. **Effect of Meat Media on Streptococci.**—Inasmuch as the fermentative activities of streptococci vary greatly with the use of meat or of meat extract in making the special media, Broadhurst suggests that all workers should state definitely whether meat or meat extract media were used throughout such investigations. Qualitative results, estimated with litmus as an indicator, are not comparable with quantitative ones, with phenolphthalein as an indicator, if meat extract is used in making the special media.

37. **Chemical Substances and Phagocytosis.**—From the results of experiments recorded in the literature and the results Arkin has obtained it appears that the effect of chemical substances on phagocytosis varies with their chemical constitution and their pharmacologic action. Alcohol, chloroform, ether, chloral, morphin and potassium cyanid depress phagocytosis *in vitro*. The substances all have an inhibitory effect on oxidation, to which their action on phagocytosis is in all probability due.

That oxidative processes play a rôle in phagocytosis is definitely shown by the fact that sodium iodoxybenzoate, which is an organic peroxid and owes its pharmacologic action as well as germicidal action to the presence of physiologically active oxygen attached to the iodin atom in its molecule, has a marked stimulating effect on the phagocytosis of streptococci and staphylococci *in vitro*. The action appears to be on the opsonin of the serum, which is rendered more active. Likewise strychnin and certain colloidal metals which have a stimulating effect on oxidative processes stimulate phagocytosis to a marked degree. The beneficial effects of improved oxygenation of the blood in infectious diseases may be due in part to the stimulating action on phagocytosis. Furthermore, substances which have a depressing effect on oxidations, as potassium cyanid, chloroform, ether, morphin, germicides, etc., have a distinct detrimental effect on phagocytosis as well as other immune reactions.

Caffein and the antipyretics which are more inert drugs have little, if any, action on phagocytosis. They have no known effect on oxidations in the body. The salts are mostly injurious to phagocytosis, to an extent depending on their toxicity, their ability to effect an exchange of ions with the salts in the cells, and their ability to combine with the opsonins. Those substances which depress phagocytosis *in vitro* have been found, when studied *in vivo*, to have a detrimental effect on the immunity reactions; e. g., the anesthetics, chloral, morphin, some salts and the antiseptics. The substances which have been found to stimulate phagocytosis at all are calcium, magnesium and mercuric chlorids; quinin; colloidal metals; peptone in dilute solution; nucleic acid; a few other leukostimulants such as staphylolysin in weak solution, potassium iodid, and perhaps alcohol; strychnin sulphate and nitrate; sodium iodoxybenzoate; salvarsan and other arsenic compounds; and possibly certain colloidal suspensions of cholesterol. It is interesting that all of these which have been studied *in vivo* have also had a favorable action, namely, salvarsan, calcium chlorid, quinin, colloidal metals (platinum, silver, gold, copper), mercuric chlorid in weak solutions, sodium iodoxybenzoate and cholesterol in colloidal suspension. Hence the action of a chemical substance on phagocytosis *in vitro* is a good index of the effect of that substance when used *in vivo*.

Arkin points out that the effects of an agent on the processes of immunity should be considered carefully when the use of that agent seems indicated in infectious diseases. The possibility of a combined therapy, consisting of the use of immune serums or vaccines together with certain drugs, suggests itself in the case of drugs which have themselves a stimulating effect on phagocytosis. The drugs may act as leukostimulants, or increase the production of antibodies, or combine with the antibodies to render them more active.

39. **Fusiform Bacillus Isolated from Blood-Stream.**—The authors claim that this is the first case on record in which the fusiform bacillus has been isolated from the blood-stream.

41. **Differentiation of Fecal Streptococci.**—From the results of the experiments cited by Fuller and Armstrong it appears that streptococci producing a high acidity in dextrose media are in general characteristic of human excreta. These strains which produce between 3.5 per cent. and 4.0 per cent. acidity in this medium are relatively abundant in human excreta. Dextrose fermenting strains are less abundant in the excreta of the horse and cow, and produce an acidity considerably less than that of the human strains.

Streptococci fermenting mannite are present in human feces in large numbers but are almost entirely lacking in the excreta of the horse and the cow. Strains fermenting dextrose, lactose and mannite (Andrewes and Horder's *S. fecalis*) comprise 65 per cent. of the cultures isolated from human stools, while only 1 per cent. of the strains from the horse and 2 per cent. of those from the cow are of this type. Streptococci fermenting lactose are comparatively rare in horse dung. Streptococci fermenting raffinose are abundant only in cow dung. Sixty-four per cent. of the strains isolated from this source ferment dextrose, lactose and raffinose (Andrewes and Horder's *S. salivarius*), 2 per cent. ferment lactose and raffinose, and 4 per cent. dextrose and raffinose. Streptococci of the salivarious type were not observed in human excreta, and comprised but 4 per cent. of the strains isolated from horse dung.

43. **Properties of Pneumonic Exudate.**—Hartman found that the addition of fatty substances and leukocytic extracts to fibrin does not increase its antigenic power. Leukocytic extracts, leukocyte residues, fatty substances from pneumonic exudates and from leukocytes (pus cells) cause non-specific binding of complement in the presence of some serums regardless of the reaction to the Noguchi test. Some specimens of pneumonic fibrin are themselves hemolytic. Fatty substances from pneumonic lungs and from leukocytes are hemolytic, but not anticomplementary in small quantities.

Normal fibrin and the non-hemolytic pneumonic fibrin, human serum, normal as well as pneumonic, inhibit the hemolysis induced by these fatty substances. The inhibitive power of the serum is contained in the globulin fraction precipitated by carbon dioxid. The four fractions of the fatty substances from pneumonic lungs and from leukocytes simulate those used as syphilitic antigen studied by Noguchi and Bronfenbrenner in their hemolytic, anticomplementary and antigenic powers. The leukocytic extracts vary to a considerable degree in their hemolytic, anticomplementary and antigenic properties. They do not serve as complement. The residues of leukocytes kept in glycerol are hemolytic and the hemolytic principles may be extracted by and demonstrated in alcohol. Extracts of leukocytes from patients with pneumonia are more strongly antigenic than those from pus-cells. The hemolytic substances associated with some pneumonia fibrin can be removed by alcohol, the alcoholic extract proving hemolytic. The anticomplementary power of normal fibrin is greatly increased by the addition of the fatty substances used in the experiments.

## Journal of Pharmacology and Experimental Therapeutics, Baltimore

*November, V, No. 2, pp. 105-213*

45 *Direct Application of Drugs to Temperature Centers. H. G. Barbour and E. S. Wing, New Haven, Conn.
46 *Paradoxical Action of Antipyrin in Partially and Completely Decerebrate Rabbits. H. G. Barbour and C. L. Deming, New Haven, Conn.
47 *Quantitative Studies on Gastro-Intestinal *Absorption of* Drugs. P. J. Hanzlik and R. J. Collins, Cleveland.

45. **Application of Drugs to Temperature Centers.**—The experiments described by Barbour and Wing show that the heat-regulating centers of the brain are directly susceptible to specific neuropharmacologic action. Besides the hyperthermiae which have previously been produced by stimulation of the region of the corpus striatum directly with puncture, electricity, cold and corrosive poisons, analogous stimulation with caffein and betatetrahydronaphtylamin can be demonstrated. Besides direct depression of this region by heat, one may obtain *an analogous depression with chloral, antipyrin, quinin and under certain conditions epinephrin.* Injected into the general circulation the minimal dose of chloral hydrate which causes a distinct temperature decrease is about 20 mg. per kilo animal. The chief factor appears to be muscular rest.

The minimal dose of antipyrin to cause a distinct fall in body temperature is about 60 mg. per kilo. Three hundred mg. is necessary to cause marked respiratory increase. Given into the region of the caudate nucleus (and lateral ventricle), chloral hydrate in doses as small as 6 mg. per kilo or over gives a distinct temperature decrease. Hyperpnea and vaso*dilation seem to be important factors. Antipyrin in doses of 20 mg. per kilo and more gives a definite fall in body temperature* with hyperpnea which appears to be the chief factor. Peripheral vasodilation, if present after this method, is very transitory. Strong alcohol, 25 per cent. or 95 per cent., in the lateral ventricle raises the body temperature as corrosives do. Five per cent. alcohol appears to have the opposite effect. Quinin hydrochlorid injected into the general circulation in doses of about 2 mg. per kilo gave a slow temperature fall of not more than 0.25 degrees. Doses ranging *from* 0 6 *to* 5.5 mg. injected directly into the brain gave *falls of from* 0.6 to 1.1 degrees with either vasodilation or hyperpnea or both. Epinephrin introduced into the brain of rabbits on winter diet always gave a fall in temperature in doses 1.01 and 0.1 mg. per kilo. No external cause was apparent. Caffein in doses of 0.6 to 1.2 mg. per kilo intracerebrally raises the body temperature usually 0.5 degree or more. Vasoconstriction and dilation *of* the pupils are noted, and sometimes signs of marked excitement. *Similar* doses in the general circulation have little or no effect on the body temperature. Betatetrahydronaphtylamin *in the general circulation* caused entirely without symptoms a rise of 0.5 degree within three hours after a dose of 0.02 gram. The same dose in the brain of a somewhat larger rabbit caused in an hour a rise of 1.1 degree with all the characteristic symptoms of this drug followed by convulsions and death.

46. ***Paradoxical Action of Antipyrin.***—Rabbits normally respond to antipyrin, in doses of 0.1 to 1 gm. (sometimes as low as 0.06 gm.) per kilo animal, by a fall in body temperature with marked peripheral vasodilation, and, where the dose is above 0.3 gm., with hyperpnea. Doses in the neighborhood of 1 gm. per kilo may cause fatal convulsions. The *cerebrum and corpus* striatum were removed by Barbour and Deming from eighteen rabbits. In nine of these cases, being those exhibiting as a rule the fewest anatomic complications, a subnormal body temperature (32.5 to 37.5 degrees the morning after *operation*) resulted. The remaining nine animals (besides two of the first mentioned nine, for the first four days after operation) behaved essentially like normal animals. The hypopyrexia animals showed signs of collapse, asymmetrical muscular disturbances, peripheral vasoconstriction and slow respiration. Their temperature condition was not due to cold, starvation or hemorrhage but to a disturbance of central *heat regulation*, probably seated chiefly in the corpus striatum. When given 0.1 to 0.4 gm. (per kilo) antipyrin they showed a definite rise in temperature rather than a fall, and a conspicuous absence of the vasodilation usually seen after the drug, as well as of the hyperpnea which would be expected from the larger doses within this range. Muscle *stiffness* was in evidence, bordering, with the larger doses, *on tonic* and clonic convulsions. Animals completely *decerebrated, including* corpora striata and optic *thalami, gave a* temperature of 26.5 degrees *to* 32.5 *degrees on the morning* after operation. Antipyrin in doses below 0.33 gm. per kilo had no effect on these *animals. Four-tenths* gm. and above always gave a definite temperature rise. Neither vasodilation nor high respiratory rates were seen. Muscle stiffness or tetanic spasms were noted. The authors conclude that the reversed effect of antipyrin on body temperature in these cases is due to the normal heat-producing property of the drug. This property is brought into prominence by operative impairment of the heat-dissipating mechanism as well as of certain normal inhibitory influences which the higher centers exercise over *the processes of heat production.*

47. **Gastro-Intestinal Absorption of Drugs.**—Hanzlik and Collins found that the quantitative absorption of alcohol from the gastro-intestinal tracts of cats and dogs is practically identical. The absorption of alcohol from the stomach and small intestine of cats and dogs is about the same; from the colon *about a fifth higher. The extent of the absorbing area* does not markedly influence the intestinal absorption of alcohol. The absorption of alcohol is scarcely influenced by the *concentration of the alcohol, although a 10 per cent. solution* is absorbed somewhat better than 5, 50 and 95 per cent. solutions. The absorption of alcohol from the intestine of cats and dogs is practically arrested at the end of half an hour after injection. The inhibitory effect is of a local nature, since the presence of alcohol in one loop does not inhibit the absorption from adjoining loops. Under certain conditions inhibition may occur systemically. The intravenous injection of alcohol inhibits its absorption from the intestine. Inhibition of the absorption is not due to *reexcretion.* The percentage absorption of *alcohol remains practically constant* within wide variations of the *systemic blood-pressure.* Changes in the *local circulation influence the intestinal* absorption of alcohol. Injury *to the* intestinal mucosa lessens the absorption of alcohol.

The inhibition of the intestinal absorption of alcohol after intravenous injection *is* due to *a slowing of the circulation* in the intestine; no such change is demonstrable after local application of the alcohol. Such lipoidal substances as olive oil, cholesterin, lecithin, soap, bile salts and bile decreased the absorption of alcohol from the intestine of cats and dogs. The absorption of alcohol from the intestine after death averaged 17.6 per cent; from the stomach 27.1 per cent. Local "narcosis" of the intestine, and changes in the concentration of alcohol are not concerned *in the inhibition of absorption.* The authors conclude that the arrest of absorption is due to a retention or "binding" of a *certain* quantity of alcohol by the intestinal tissues.

51. **Immunity in Experimental Cancer.**—Levin's studies lead him to believe that Bashford's theory of a *specific* connective-tissue scaffolding has *no* general application in the explanation of cancer immunity. The conditions appear to be quite different when the tumor is inoculated directly into an *organ* instead of subcutaneously. *In this case* the first visible step is not the formation of a connective-*tissue stroma*, but

the inoculated cells immediately begin to proliferate and invade diffusely the normal tissue.

On the other hand, in an immune animal the tumor cells inoculated into an organ do not grow but die and are invaded by an extensive connective-tissue stroma like any other dead foreign body. Consequently, the immune organism does not lack the capacity to form connective-tissue scaffolding, and such an incapacity can no more be considered of a general importance in the elucidation of the phenomenon of immunity in experimental cancer than the lack of specific chemical food. Levin found that the inoculable tumors of the white mice and rats, as a general rule, grow just as well when inoculated into a parenchymatous organ as when inoculated subcutaneously. On the other hand, an animal resistant to a subcutaneous inoculation also resists an inoculation into an organ.

In his experiments with the Flexner-Jobling adenocarcinoma of the white rat, Levin noticed that while the tumor grows when inoculated subcutaneously or into any other organ in a large percentage of animals used, it does not grow when inoculated into a normal testicle. But when a testicle is treated previous to the inoculation either with an emulsion of Scharlach R in oil or an emulsion of ether in water, there takes place in the organ an inflammation accompanied with a proliferation of the intertubular connective-tissue, and then the inoculation of the same tumor into the organ becomes successful. The failure of the growth of the tumor in the normal testicle is not due to a general condition of the organism, but to a local action of the testicle on the tumor cells. The percentage of animals which are generally resistant to a subcutaneous inoculation is very small, and all the animals used for the inoculation into the testicle could not have been resistant to the growth of the tumor. Nor is it due to the mechanical influence of the tunica interfering with the expansion of the organ by the growing tumor, nor to the lack of specific food in the organism of the host. Investigations have shown that other inoculable tumors grow well in the testicle. The mechanism of this local resistance can be due only to an inhibitory action on the cells of this tumor of the cells of the tubules of the testicle. This investigation shows also that it is possible to render the same testicle artificially susceptible to the growth of the tumor.

In another more recent investigation Levin found again a striking proof of the possibility of a certain organ reacting differently toward the growth of an inoculable tumor than the rest of the organism. He repeated Uhlenhuth's experiments with the difference that the second inoculation was done not subcutaneously but into an organ. The results obtained coincided well with the results of Uhlenhuth. He then varied the experiments so that the second inoculation was not done in one organ, but in two organs—liver and spleen—simultaneously. The results obtained were quite unexpected. When the operation was radical and the subcutaneous tumor did not recur, then the secondary inoculation was not successful in any organ. On the other hand, when the operated subcutaneous tumor recurred then in a certain number of cases the secondary inoculation succeeded in both organs; in another series of experiments the secondary inoculation succeeded in one organ and failed in another. All these experiments show conclusively that the phenomena of immunity in experimental cancer cannot be explained by specific food relationship. There must exist a certain as yet unknown kind of an active inhibitory influence of the organism of the host on the cancer cells.

79. **Influence of Disease on Civilization.**—Vaughan concludes as follows: In the future the training of the medical man must be developed largely with a view to his broader relations to the public. His proper function must be to prevent, rather than cure disease. The physician's duties are to become more and more largely official, in the sense that his services are to be rendered to the community, and not exclusively to the individual. Vaughan is quite sure that the time will come when people will go to the physician to find out whether they are really well or not, and not wait until they know they are ill. They will go for examination and advice, rather than for treatment. Ultimately the time will come when every one will be examined twice, or oftener, each year, and no two consecutive examinations will be made by the same physician. A record will be kept of each examination, and when the individual ultimately dies a careful autopsy will be held in every instance. At first these things will be voluntarily done by intelligent people and, later, others, seeing its advantage will adopt the rule. Finally, it will be compulsory with all, and will result in great good to the whole. The value of a custom of this kind in case of many of the infectious diseases, both to the individual and to the public, is evident.

82. **Social Service Appliea to Dispensary and Hospital Work.**—Social service work in Klaer's opinion has come to stay. It has already regenerated outpatient departments so that this phase of hospital activity will soon take a position equal to that of the ward as a source of study or research, and a much more important place than the ward in the line of preventive medicine. It must, however, always rest on and be closely allied to the medical side of the work, and there must always be the closest cooperation between physicians and

social workers, if both are to work for the best interests of the patient. Accurate diagnosis of medical conditions is absolutely essential to effective social service work. The graduate nurse will find a large field in certain special lines of social service, but even in these lines she must acquire the social service point of view, either by study or experience. In many phases of the work the nurses' training may be regarded as hardly necessary.

Physicians cannot afford to overlook this great auxiliary to hospital or outpatient treatment either in large or small hospitals. It is the department which makes effective the physicians' ideas and instruction and will bring about cures, where, without its help, failure is bound to follow. It will, moreover, be the department through which hospital efficiency may be checked up, and thus set or raise the general standards of this work.

85. **Care of Defectives.**—Sterilization, Murdock says, is at best a partial remedy, as in all probability only those in the scale so low in mentality that the likelihood of parenthood is extremely improbable would be reached. Sterilization is not actually operative in one of the eight states that have passed sterilization laws. Sterilization would not be a safe and effective substitute for permanent segregation and control, and it is to this permanent segregation and control that we must look as the rational policy for controlling feeble-minded.

7 Epidemic of Specific Parotitis in Schoolchildren. A. Graham.
8 *Intestine as Pathway of Infection to Tubercle Bacillus, with Special Reference to Part Played by Diarrhea. L. Findlay.

6. **Scarlatinal Infection.**—The fact that Higgins isolated typical bacillus diphtheriae from the scarlatinally infectious "primary" cases in 25 per cent. of instances, but only in 7 per cent. of those cases of scarlet fever whose return from hospital had not produced return cases, and in 7 per cent. also among normal schoolchildren, he thinks, seems to show that the presence of this germ in the nose or throat of patients with scarlet fever is often associated with a prolongation of the period of scarlatinal infectiousness, and that the presence of the germ is indicative of an increased probability of such infectiousness.

8. **Intestine as Pathway of Infection.**—Findlay found that healthy rabbits can be infected by the ingestion of large amounts of bovine tubercle bacilli. The bacilli can pass through the apparently intact intestinal mucous membrane and reach the mesenteric glands within a period of six days; this, however, does not frequently happen. When infection occurs the intestine is invariably the seat of lesions, and thus tuberculosis of any origin, other than the intestine, is always a secondary infection when the bacilli have entered by the intestinal route. Catarrh of the intestine does not favor the passage of the tubercle bacillus through the wall, but allows of a more constant, and also of an earlier and more widespread infection of the bowel, and in this way facilitates dissemination. Healthy rabbits apparently cannot be infected by the ingestion of large amounts of the human tubercle bacillus. Rabbits just recovered from intestinal catarrh developed tuberculosis after the ingestion of human tubercle bacilli. With the human type of organism a local lesion, though always present, may be slight in comparison with the diseased foci in the mesenteric glands. It would seem that the best means of combating the spread of bovine infection in childhood—until tuberculosis of cattle is eradicated—is in the avoidance of everything likely to cause intestinal catarrh.

12. **Treatment of Gonorrheal Epididymitis.**—In applying passive congestion to a testicle for the treatment of gonorrheal epididymitis, Wilson uses a strip of lint 1½ inches wide, a fine piece of rubber tubing and a pair of Spencer Wells forceps. The cord on the affected side is encircled just above the testicle by the strip of lint, which is continued round between the two testicles along the median raphe of the scrotum. Over the lint is applied the rubber tubing, which is tightened to the required extent and secured by artery forceps. (The required extent being such that no pain results after the application; instead, the patients describe a comfortable warming sensation with immediate relief of pain.) Pain after application implies that the tubing is too tightly applied, and suggests that it should be loosened. A few moments after adjustment the enclosed tissues assume a purple color resembling a ripe plum. The treatment is applied for an hour the first day, where possible, increasing daily up to eight hours. But in some very acute cases half an hour will be all that the patient can stand at first. Where practicable, however, Wilson says it will be found that the duration of disease is in inverse ratio to the length of daily application of treatment.

45. **Polyvalent Tuberculin and Types of Temperature Reaction.**—A rise of temperature, even of half a degree Fahrenheit above the mean, occurring within seventy-two hours of an injection of tuberculin, Sutherland maintains, is to be regarded as a reaction. A rise of temperature reaching its maximum within twenty-four hours of an injection is an immediate reaction, and may occur four hours after the injection. A rise of temperature reaching its maximum within forty-eight hours of the injection is a delayed reaction. A rise of temperature reaching its maximum within seventy-two hours of the injection is a progressive reaction. In their order of severity these types of temperature reaction are as follows: (a) immediate reaction with a fall by crisis—increase dose; (b) delayed reaction with a fall by crisis—repeat dose; (c) immediate reaction with a fall by lysis—reduce dose by one-fifth; (d) progressive reaction with a fall by crisis—reduce dose to one-tenth; (e) progressive reaction with a fall by lysis—stop tuberculin.

47. **Abderhalden's Method in Carcinoma.**—There is, in Brockman's opinion, sufficient evidence to show that the blood of persons suffering from carcinoma contains a substance absent in the blood of all others, and that this substance has a proteolytic action on the carcinoma tissue only. There are also several factors which point to its being of the nature of a ferment. If the serum from a patient is left to get stale it becomes inactive, but the addition of a trace of fresh human serum will activate it again. The reaction takes place best at 37 C. At room temperature the reaction does not occur, while heating the serum to 55 C. for five minutes inactivates it beyond recall. If, then, as is maintained, this substance is of a protective nature, it would be natural to expect to find it present in larger quantities in patients who were in good general health. The results of these tests point strongly to such being the case. Brockman has noticed throughout the whole series that a patient with a growth of the tongue or of the breast who is in good general condition will give an intensity of coloration in twelve hours which a patient in a low state of health would fail to give in twenty-four hours.

56 Spontaneous Dislocation in Joint Disease. (Les luxations spontanées vraies dans la tuberculose articulaire et dans les arthrites en général.) P. Bertein.

54. **Pain from the Surgical Standpoint.**—Picqué comments on the comparatively slight attention paid to pain by the surgeon, urging that study of the pain is liable to prove a useful guide in various ways. He states that he knows of only one article on pain written by a surgeon in recent years. Richet, the physiologist, to whom a Nobel prize has been awarded, declares that the capacity for feeling pain is more developed in proportion to the development of the mind, and he regards pain as the fundamental element in human progress. Picqué defines pain as generally merely the special perception of some peripheral organic trouble. As a rule, the comparatively insignificant lesions are the ones that induce the severest pains. By comparing the subjective with the objective findings it is possible to determine to what extent the mind participates in causing the pain. Championnière has warned that the surgeon in his examination may create pain for the first time, and that once thus inaugurated, the pain may persist indefinitely. The questions of the physician are liable likewise to call pain into existence or first cause a realization of existing slight pain.

58 Radioscopy of Tracheobronchial Lymph-Nodes in Children. D'Oelsnitz and Paschetta.
59 The Intradermal Reaction to Injection of Serum. (La réaction sérique intracutanée.) J. Michiels.

57. **Uremia in Children.**—Nobécourt declares that the pediatrist should apply in his practice the various means of investigation used for adults but he should beware of applying to a child the conclusions drawn from the responses in adults. Uremia, for instance, in older children as with adults, is a consequence of nephritis. But the highest proportions of urea in children in his experience were found with acute and transient nephritis. The prognosis is less favorable when the urea is mild but persisting, this chronic character suggesting a profound and progressive lesion in the kidney. In infants and young children nephritis is less often responsible for the uremia; it appears in acute gastro-intestinal disturbance and bronchopneumonia. High azotemia, unless briefly transient, seems to be the chemical substratum, he says, of athrepsia. The discovery of urea persisting in the cerebrospinal fluid, even in a low percentage, indicates a grave prognosis. Urea up to 0.5, 0.7, 1 or 3 gm. was found in the cerebrospinal fluid of eleven out of eighteen infants with athrepsia; the proportion varied, but the findings were constantly positive till death. Necropsy revealed no signs of tuberculosis or syphilis, while in another series of tuberculous or syphilitic infants, some with pneumonia or digestive trouble, the urea content was constantly normal or below. The athrepsic babies present the uremic syndrome similar to that in adults: gastro-intestinal disturbances, lack of appetite, progressive emaciation and torpor. Uremia in infants may be accompanied by symptoms on the part of the nervous system suggesting meningitis but differing in that the gaze is not so fixed and there is myosis instead of the mydriasis of meningitis. A negative tuberculin reaction also speaks against meningitis.

### Bulletin de l'Académie de Médecine, Paris

*October 14, LXXVII, No. 31, pp. 209-222*

60 *Training the Muscles of the Ear in Treatment of Deafness. (Du traitement de la surdité par la gymnastique auriculaire et les exercises acoustiques.) M. Fernet.

61 Sexual Perversions a Form of Disease. (Inversion sexuelle et pathologie mental.) P. Ladame and Magnan.

*October 28, No. 33, pp. 284-323*

62 Epileptic Myoclonus. Four Cases. Oddo and Corsy.

60. **Warding Off and Treatment of Deafness by Exercising the Muscles of the Ear.**—Fernet ascribes the benefit from exercising an organ to the consequent improved circulation and better nourishment, enabling it to throw off traces of pre-

ceding disease, and to the better adaptation to its function progressively acquired by practice, but, above all, to the training of the auxiliary organs which sustain and reenforce the lagging organ.

Functional reeducation based on these principles has been successfully applied in treatment of the infirmities in chronic rheumatism and tabes, but the prospects are still more promising in training the hearing in case of encroaching deafness in the elderly or after otitis media. The muscles of the outer ear and middle ear and of the eustachian tube are generally supposed to be beyond the control of the will, but children can frequently voluntarily move the ears and part of the scalp and some become quite expert at it. Fernet thinks that this faculty is lost simply from lack of exercise in adults, but if it can be acquired anew the muscles of the internal ear, which probably share in the movement of the outer muscles, will be effectually exercised. All the above muscles are innervated by the facialis nerve, which explains their concerted action. Even if only one of the above muscles can be exercised, the benefit will extend throughout the whole group of muscles as others contract with it. When only one ear is deaf, the individual generally uses the good ear exclusively, leaving the deaf ear to atrophy and the spark of hearing left soon dies out; if the ear were systematically trained to listen the spark might be kept alive and grow brighter.

The exercises of the muscles may be done in three series, those of the face, then the scalp and auricle, and lastly, those of the eustachian tube. The first series is mainly by grimaces of the face, contracting in turn the muscles of the lips, nostrils, eyelids, doing the exercises slowly and repeating them, aiming to reach the ear. Medical men knowing the anatomy of the parts can train their muscles very effectually in this way; others need a monitor to show them how. With a little training one can learn to move the scalp; especially if it is loosened with a little massage beforehand. The frontal and then the occipital muscles can be contracted alternately, forcing the top of the scalp back and forth, and then the muscles above, behind and in front of the ear. A series of these exercises gives one an unmistakable impression that the depths of the ear are roused from their torpor and that the sound waves have better access. The muscles of the eustachian tube are exercised by a kind of swallowing movement with simultaneous contraction of the muscles of the upper pharynx and velum. A deep inspiration followed by an abrupt expiration through the nose ventilates the tube, and other exercises aid in training the muscles of the tube as they move in concert with adjacent muscles.

The hearing proper should be exercised and trained. Listen with the deaf ear, the ear that hears most defectively; listen the harder with it because it is sliding down into deafness. Fernet's methods have proved very useful in many cases, especially in those in which the trouble in hearing is connected with transmission of sound waves by the middle ear—the most common cause of deafness. Physicians particularly need good hearing, and instead of accepting deafness with the fatalism of the oriental, they should rouse up and fight it.

65. **Mammary Tumors.**—Gosset and Masson state that cystic disease of the breast unquestionably predisposes to cancer. Microscopic examination in cystic disease of the breast may reveal the cancer in its earliest incipiency and thus permit a truly radical cure. Among the seventy-five cases reported and compared, cancer had developed in the in twenty-nine cases of cystic disease of the breast. Only three were found free from cancerous degeneration. The tumor was an epithelioma in fifty-two of the seventy-five cases, including twenty-five with preceding cystic disease, and three with tuberculosis.

67. **Surgery of the Brain.**—Stieda describes in detail the case of a girl of 5 from whose brain a tumor as large as a hen's egg and weighing 125 gm. was removed over a year ago. The symptoms improved remarkably or subsided entirely. This case and several others he reports teach the necessity for operating for brain tumors at two sittings and under local anesthesia, never tamponing or draining; if a plastic operation is necessary, fascia from the thigh is the best material for the purpose. Severe bleeding can be arrested easily and promptly by pressing with scraps of muscle. The case of a young woman is described who has very little disturbances of any kind to show at present, eight years after a partial operation on a glioma in the left central lobe near the center for the arm. As the growth was not circumscribed, it could not be entirely removed; a piece 2x3 cm. was cut out. The tumor has evidently retrogressed during the eight years since to a remarkable extent.

68. **Plastic Operation on the Esophagus.**—The young woman in the case described drank sulphuric acid with suicidal intent, and Stieda gives an illustrated description of the technic with which he later provided her with a new esophagus, made from a skin flap and connected with the stomach by a stout rubber tube, pushed up tight into the lower end of the new esophagus.

75. **Invagination of the Intestine in Children.**—Becker reports twelve cases he has encountered in the last ten years, all chronic but four. In the four acute cases the children were from 5 months to nearly 4 years old and three died. The only child that recovered was the only one treated by rectal injections alone. In the eight chronic cases, that is, with invagination for more than five days, five of the children died. His experience has convinced him that the proliferation of bacteria and production of toxins in the invaginated intestine are what reduces the resisting powers to such a low ebb. The aim in treatment should be to get rid of this source of intoxication as soon as possible, and this is best accomplished, he thinks, by resection of the invaginated portion, followed by entero-anastomosis. The earlier the operation is done the better the results with children over a year old.

81. **Operation on Peripheral Motor Nerves for Spastic Paralysis.**—Bundschuh has applied in three cases Stoffel's method of weakening the contracted muscle by severing certain of its nerve fibers. The stretch innervated by these fibers ceases to be contracted after they have been divided, and flaccid paralysis of this stretch takes the place of the former contracture. The muscle by this means loses its excessive nervous energy and the normal balance between it and the antagonist muscle is restored. Bundschuh's patients were 3 and 12 years old, with Little's disease or paralysis from early encephalitis. In two of the children the results are highly satisfactory but in the other the triceps surae was evidently not weakened quite enough, and there is still some contracture of the foot which it is proposed to correct later. He emphasizes that the aftercare must be regarded as of equal importance with the operation. Intelligent cooperation on the part of the family is indispensable.

83. **Ligation of Iliac Artery.**—Strauss relates a case in which gangrene developed in the leg after ligation of the external iliac artery under aseptic conditions and with no complications; the artery had required ligating on account of its tearing from traction of adhesions during an operation for inguinal hernia in a man of 70. He says that this occurs so rarely after ligation of the external iliac, in comparison with ligation of the common iliac artery, that the former deserves the preference in all possible cases. The ability to bear ligation without gangrene depends on the functional capacity of the heart, and this should be carefully estimated beforehand. Korotkow's test has proved very useful for this when considering an operation for aneurysm: He compresses the artery above the aneurysm and determines the blood-pressure with the manometer applied below, to the toes, for instance. This permits estimation of the force of the collateral circulation and thus warns of a predisposition to gangrene in case it is found low. If compression is applied above and below the lesion, thus excluding this stretch from the circulation, the blood-pressure at the toes will be approximately what it would be after the stretch of artery had been resected.

84. **Spiral Incision for Varices.**—Rauch says that the results in two of his five cases were most excellent; there has been no recurrence during the years since of the extensive varices and torpid ulcers with elephantiasic changes in the skin. Both these patients had been previously treated by other measures, including operative, but without result, and both had their earning capacity restored in two and a half and three and a half months, by the spiral incision. In the other cases the complete procedure could not be applied and the results were less perfect, but full earning capacity was regained in seven to twelve weeks. The operation is severe and necessarily accompanied by considerable loss of blood so that it is indicated only in the extremely rebellious cases of varicose enlargement of veins. Rauch cites in conclusion the surprisingly favorable results found by Geinitz on a recent reexamination of six patients on whom he had performed the spiral operation nearly two years before.

88. **The Thymus and Thyroid in Their Reciprocal Relation to Exophthalmic Goiter.**—This long article is accompanied by six large charts showing the minute results of the investigations reported, besides five pages of schematic representation of conditions in a number of clinical cases. The data presented seem to show that the thymus and thyroid in exophthalmic goiter work in harmony to a certain extent, but in other points they work against each other. The writers, Capelle and Bayer, were the first to call attention to the possibility that a thymectomy may have as favorable an influence as thyroidectomy in certain cases of exophthalmic goiter. They report a new case of this kind: A woman of 27 developed the symptoms of Basedow's disease in a severe form; palpitations, tremor, diarrhea with vomiting, loss of 24 pounds in three months, the hair falling out, the menses suspended, and the neck growing a very little larger. There was only slight tendency to protrusion of the eyeballs, but they had a peculiar stare. The thyroid showed remarkably slight changes and the severity of the clinical symptoms in comparison with the almost entirely normal aspect of the thyroid suggested that the thymus might be responsible for the syndrome. Roentgenoscopy and palpation rendered a persisting thymus almost certain, and it was removed. Prompt improvement followed; the woman gained 6 pounds in three weeks, menstruation became normal, the pulse dropped from 130 to 95, and the condition now, five months later, may be regarded as practically normal. The thymus was not materially enlarged but showed some hyperplasia of the medulla, less of the cortex, while the content in eosinophil cells was high.

The tables of the metabolic findings in a number of typical cases confirm the assumption that the thymus and thyroid may both be incriminated in Basedow's disease, and that the symptoms vary as one or the other predominates in the production of symptoms. The data presented seem to show that the predominance of symptoms for which the sympathetic nervous system is responsible points to the thyroid as chiefly to blame, while the predominance of vagus symptoms points to the thymus. In dubious cases the simpler operation, thyroidectomy, should be done, but if symptoms persist the thymus should be resected also. In a case with much exophthalmos, much excited heart action, with tendency to fluctuations of temperature and trophic disturbances, the trouble can be referred to the thyroid. On the other hand, in cases with only slight protrusion of the eyeballs, with pronounced subjective heart disturbances but the pulse not altered to correspond, with sweats, diarrhea and dyspepsia dominating the clinical picture, the blood modified according to the Kocher type, and there is an area of dulness over the thymus region and a tendency to myasthenia—this clinical picture incriminates the thymus, and thymectomy should be done first if the thyroid shows no changes proportional to the severity of the Basedow picture. They have operated in three cases on these presumptions, and two of the patients were practically cured; the third died from cardiac paralysis half an hour after the operation. They report further trials of organ therapy, thymus and ovary tissue, but their experiences have been too few for conclusive judgment.

They report further some experiments with injection of epinephrin in Basedow patients to determine whether the sympathetic or vagus nerves were predominantly involved; the findings are compared with those in healthy persons. They gave a subcutaneous injection of 0.001 gm. epinephrin and repeated in half an hour. A response with profuse sweating, palpitation and tremor was always obtained in the severe cases, as also polyuria and glycosuria. When the sweating, polyuria and glycosuria are extremely pronounced, the sympathetic system is mainly involved. The blood changes also under the epinephrin. The condition returns to normal more promptly in the sympathetic system cases; the lack of repair seems to characterize the vagus cases.

96 *By-Effects of Arsenic and Salvarsan. (Nachtrag zu meinen Arbeiten über die Nebenwirkungen des Salvarsans.) R. Obermiller.

89. **Cerebellum Tumors.**—Oppenheim and Borchardt recently demonstrated a robust young man of 22 in apparently good health, except that vision in one eye is reduced somewhat and when the eyes are shut there is slight staggering. Fifteen months before they had removed a fibrosarcoma from the vermiform process of the cerebellum; it was not circumscribed and considerable portions of the process had to be cut out. The part left was vigorously cauterized. Two previous attempts during the preceding six weeks had had to be interrupted on account of collapse, and after the main operation artificial respiration had to be kept up with brief intervals through the day and next night. The respiration stopped at times completely and then alternated with Cheyne-Stokes with persisting tracheal râles; the pulse kept good. After twenty-four hours the respiration proceeded naturally once more but then the heart repeatedly seemed to be failing. This was successfully combatted with camphor and caffein. The two-hour operation was done under local anesthesia, with a few whiffs of ether at times when the patient complained of discomfort from the position of his head. An equally favorable outcome is reported in the case of a child of 7 who had a tumor the size of a walnut removed from the right hemisphere of the cerebellum. It had already entailed total amaurosis. Eighteen months after the operation the girl is not only in perfect general health but vision has returned so she can count fingers at half a meter. This is the only case of restoration of vision which Oppenheim has encountered.

90. **Acquired Deformity of the Upper Femur.**—Axhausen gives an illustrated description of some cases of tumefaction in the upper femur of various origins. The trouble was a fibrous ostitis in some cases; it was restricted entirely to this one site, and was of several years' standing, up to twenty years in one case. Operative measures seem indicated in such cases and are generally required by a spontaneous fracture sooner or later. The Wassermann will exclude syphilis if there is an unfounded suspicion that the trouble is a syphilitic bone lesion. In another case the trouble in the upper end of the femur in a woman of 71 proved to be a circumscribed focus of severe, pure osteomalacia; no other bones were affected. This is the first instance on record, he thinks, of an extremely severe form of osteomalacia restricted to one bone. In two other cases the large tumor had developed after a fracture but it simulated malignant disease; the patients are both living, several years since the examination. This excludes cancer; the trouble is probably merely excessive callus production at the site of an old fracture; both patients are tabetic.

92. **Exanthematous Typhus.**—Few persons nowadays have had such experience with this disease as Hegler and Prowazek, who studied it in four immigrants at Hamburg and then in hundreds of cases in Servia during the Balkan War. The blood was examined with special care and certain changes were found which are apparently typical; they were never found in the blood of typhoid or measles patients. The disease does not seem to be transmitted by direct contact but all their experiences confirmed transmission by the louse. Inunctions with eucalyptus oil regularly before entering the typhus hospital protected them against the disease, aided by the fact that the patients had all been freed from vermin on entering the hospital.

94. **Simple Test for Iodin in Urine or Saliva.**—Lesser stirs with the end of a match a little calomel into a few drops of the urine on a slide or card. If it contains iodin, the calomel turns bright yellow. Iodin in the saliva is shown up in the same way if the patient spits on a little calomel. This calomel test, he says, is extremely delicate and reliable. Another way to reveal the presence of iodin is by touching the tongue with a silver nitrate stick. The white mark left by the caustic is not white but yellow in case the individual has been taking iodin.

96. **By-Effects of Salvarsan.**—Obermiller ridicules the attempts to explain the mishaps after salvarsan by attributing them to anything except the toxic action of arsenic which salvarsan shares with all other preparations of arsenic.

99. **Hyperemia in Treatment of Disease in the Urinary Passages.**—Frank refers in particular to inflammation with infiltration, and says that nothing loosens up the tissues and promotes absorption so effectually as the application of local heat. For several years he has been working to perfect appliances to induce local hyperemia, and here gives an illustrated description of a number of them. They are connected with an ordinary electric-light wire with a thermometer to regulate the heat. Patients bear without discomfort a temperature of 55 C. in the urethra, and the catheter can be left in place at this temperature for twenty-five or thirty minutes. The relief of pain is marked, and he states that under all circumstances a warm catheter can be introduced much easier than one at ordinary temperature. He has found that some patients otherwise requiring local anesthesia before the catheter can be introduced readily bear the introduction of a catheter heated to 30 or 40 C., and the dilatation can be carried much farther with heated catheters. He was one of the first to recognize the advantages of Bier's hyperemic treatment for urologic practice, and five years' experience has only confirmed its importance. The appliances described adapt it for various organs, and the pathologic changes retrogress much more rapidly, he declares, more certainly and more completely than is possible otherwise. He adds that Bier's hyperemic treatment registers its finest successes in treatment of chronic inflammatory processes in the urinary and sexual organs, reducing the pain, destroying bacteria or attenuating them, while promoting absorption and resolution and better nourishment of the parts.

101. **Enlargement of the Prostate.**—Jacobsohn argues that the prostate and seminal vesicles are cooperative organs, and he believes that it is possible by influencing the seminal vesicles to act indirectly on the prostate. He sought to accomplish this by radio-active treatment of the seminal vesicles, and reports three cases in detail in which the moderately enlarged prostate subsided enough, in two, to permit practically normal bladder functioning. The prostate materially retrogressed in the other case after ten exposures, but the bladder function is not improved as the disturbances were of many years' standing in a decrepit man of 78. Jacobsohn thinks that this indirect radiotherapy of hypertrophy of the prostate has a promising future and a logical basis in the physiologic connection between the accessory sexual glands.

116 Sugar Content of Transudates and Exudates. C. Hegler and O. Schumm.

108. **Intestinal Auto-Intoxication.**—Roos regards the toxins produced by bacteria in the intestines as the ones responsible for the symptoms of what we call intestinal auto-intoxication. He says that Strassburger found that a fifth of the dry substance of the stool is often composed of bacteria, and in pathologic conditions without much diarrhea the amount may be more than twice this. Roos used lactic acid bacilli in treatment of rebellious constipation before Metchnikoff published his works on the subject, and he states that the benefit from this has long been known empirically; acid fruits, vegetables or milk containing lactic acid and lactic bacilli have been found particularly wholesome for ages in all parts of the world. Peoples that consume much milk are generally exceptionally robust and long-lived. Milk becomes acid during lactic acid fermentation, while meat under the same condition putrefies; sugar protects organic substances against putrefaction. White cheese has a marked effect in reducing putrefaction in the intestine; Baumann presented evidence that the ethereal sulphates—products of intestinal putrefaction—are materially reduced when white cheese is eaten. Pure casein does not have this property. The white cheese probably takes the milk sugar with it into the lower parts of the bowel. Roos remarks that Metchnikoff's new treatment with the peptolytic glycobacterium, to be taken with considerable potato, forms a new method of treatment which is closely analogous to a dish very popular in Roos' country, namely, boiled potatoes with sour milk-sauce (*gesottene Kartoffeln mit Sauermilch*). Here again, he exclaims, as so often happens, observation and experience, empiricism, have long preceded the scientific explanation of the facts observed.

Abnormal bacterial transformations in the intestines may be combated by regulation of the diet, but it must not be forgotten that the putrefaction may occur not so much in the food particles in the intestine as in the serous fluid poured out from the intestinal walls, which is particularly liable to putrefy easily. Dieting would not affect this; astringents should be given the preference, but the main reliance should be on copious injections, washing out from the bowel the putrefying substances. Diastatic ferments may be useful with fermentation dyspepsia and insufficiency of ferment production. Ordinary sour milk is useful also, but yoghurt is more effectual as the lactic acid bacilli in the latter are more resistant and produce more of the lactic acid. In conclusion he remarks that sourkraut may owe its reputation for wholesomeness to the lactic acid carried with it into the lower bowel; possibly a regular course of sourkraut might be useful in some cases.

110. **Abderhalden's Serodiagnosis in Internal Medicine.**—Bauer reviews the literature on this subject to date, all the evidence tending to confirm the existence of specific ferments, digesting certain organ tissues. At the same time it must not be forgotten that in most cases the ferments are not absolutely specific but tend to be polyvalent. A kind of codigestion (*Mitabbau*) may occur like the coagglutination in serology. It is only a question of time, however, when the technic will be perfected to avoid these group reactions. At present we are only at the beginning of the harvest to be reaped from Abderhalden's method.

112. **Covered Perforation of the Stomach.**—Schnitzler reports two cases recently observed in which the syndrome indicated perforation of a gastric ulcer but then the symptoms subsided and there was recovery in the clinical sense although roentgenoscopy revealed the presence of an unmistable boring ulcer. He warns that operative treatment should never be deferred or omitted in these cases; the perforation is liable to cause serious trouble anew at any moment. Both his patients were young women and in the first case the opening had become plugged by the pancreas.

114. **Radial Paresis from Lead-Poisoning.**—Zondek reports a few typical cases to call attention to the difficulty in flexing the hand backward on the wrist, which he noticed in a few cases as the first sign of lead-poisoning. The grasp of the hand was abnormally weak, but otherwise the condition caused no disturbance. He gives illustrations, and remarks that this radial paresis may prove useful in differentiation.

128 *The Physician and the Tailor. (Die Hohe Schule für Aerzte und Kranke. IX.) M. Nassauer.

117. **The Pressure in the Cerebrospinal Fluid with Eye Disease.**—Heine called attention some time ago to the increase in the pressure of the cerebrospinal fluid as a sign of otherwise latent irritation of the meninges with certain affections of the eye, such as keratitis, herpes of the cornea, etc. He shows by a few examples that a scrap of iron in the eye, contusion or other injury or affection is liable to increase the pressure on the brain, the headache, vertigo and other signs of abnormal pressure keeping up for weeks in some cases. In others there may be no signs of abnormal pressure. His experience confirms the assumption that a psychic element plays a large part in the syndrome.

121. **Abderhalden's Serodiagnosis in Psychiatry.**—Beyer's findings in fourteen cases confirm the possibility of utilizing the specific reactions in differentiating between dementia praecox and other mental affections, and excluding simulation. In the six cases of dementia praecox, testicle or ovary and cortex tissue was digested at every test, while the response was constantly negative in the manic-depressive cases, in simple syphilis, etc.

123. **Non-Tuberculous Disease of the Apex.**—Litzner writes from the Rehburg sanatorium to describe a number of cases in which an apical process had simulated tuberculosis. He shows that a whole series of physiologic and pathologic changes may occur in the apex which have nothing to do with tuberculosis. With a process due to inhalation of dust, the percussion and auscultation findings and possibly coughing up of blood are not as a rule accompanied by fever, and the general health does not suffer so much as with tuberculosis. In one of the cases the influenza bacillus was found constantly in the sputum but never tubercle bacilli, and the tuberculin test was constantly negative. This patient had been under treatment for tuberculosis for nearly a year and during the year since she has had hemorrhage from the lungs, the seventh in the course of eight years, but she has never had fever nor night sweats; no sputum, but occasional cough. Recently there has been some expectoration but the bacteriologic findings are still the same as before: influenza bacilli and no tubercle bacilli. It is important to examine the sputum for fungi. With an infarct in the apex, the sudden onset of symptoms and the usual heart disease point to the correct differentiation; pleurisy may follow if the infarct reaches to the surface. In two cases the trouble was a tumor; there is dulness over a tumor while respiration does not seem to be totally arrested. Echinococcus disease may simulate a tuberculous process, but it can be differentiated by a puncture-fluid free from albumin but with large salt-content.

124. **Acute Pancreatitis.**—Hofmann reports the successful outcome in a case of acute pancreatitis in which he had intended to excise the necrotic portion of the pancreas, but desisted on account of uncontrollable hemorrhage after merely

cutting the gland across after separating the capsule over the anterior aspect of the pancreas. He adds that with acute pancreatitis there is a strip of tenderness running across the abdomen, the pain on pressure being equally acute all along this strip corresponding to the outline of the pancreas, from the epigastrium to the spleen, along the left costal arch.

126. **Hot-Air or Moving-Air in Treatment of Large Wounds.**—Heisler has no apparatus to apply the douche of hot-air which Bergeat extols as particularly useful in promoting the healing of extensive granulating surfaces. To secure a similar action on the wound, he has his patients expose the limb to the stream of air blown from an ordinary electric fan or other ventilator. The current of briskly moving air dries up the wound rapidly and healing proceeds with remarkable promptness. The moving air answers all the purposes apparently of a superheated air-douche; it proved particularly useful in hastening the healing of rebellious leg ulcers and discharging eczema.

128. **The Physician and the Tailor.**—In this ninth instalment of what Nassauer calls "The High-School for Physicians and Patients," he describes a doctor's experience in collecting his bill for delivering a primipara of 40. Delivery had been difficult and tedious, and some lacerations required suturing which he attended to at once. The elderly tissues did not hold the sutures well, and he told the woman to come to him later to have a stitch taken. When his bill was rendered, the husband, a tailor, sent the money for only half the amount of the bill, with a line saying "You overrate your work and you overrate my means. I had to have my wife's laceration sutured by Dr. Elbogen and I deduct the amount of his bill. The workman must pay for any damage he does." The physician wasted no thought on the writer of the note, but he imagined he could hear Dr. Elbogen's words as he repaired the laceration: "A tear of this kind is liable to happen to any one, but I have been very fortunate and have never had any in my practice. Why did not the obstetrician finish his work? perhaps he did not happen to have the necessary instruments with him. But the tear is bad now, and must be attended to at once. Come to the office and we'll have it fixed up in no time." "Elbogen's words were balm to the tailor's sordid soul," Nassauer concludes, "and their two hearts beat as one."

### Therapie der Gegenwart, Berlin

*November, LIV, No. 11, pp. 481-528*

129 *Physical Measures in Treatment of Joint Disease. (Die physikalische Therapie der Gelenkkrankheiten.) P. Lazarus.
130 Experience with B [illegible] Bergmann.
131 *Treatment of Tab[illegible] J. Donath.
132 **Pertussis and Its* [illegible] Ochsenius.

129. **Physical Measures in Treatment of Joint Disease.**—Lazarus discusses the various physical measures that can be applied in treatment of acute and chronic arthritis, and describes the preferable technic. In chronic joint affections external treatment is generally more effectual than internal, contrary to what is observed with acute infectious polyarthritis. He says in conclusion that the results of physical measures often surpass those with drugs, and the general practitioner can apply them with simple procedures if only he will practice the proper technic. Physical measures have another important advantage in that they are applied by the physician himself, and thus more intimate relations develop between the physician and the patient than when he merely gives a prescription to be filled by a druggist. The physical measures should not be restricted to the hospitals and sanatoriums but every physician should master them, especially active and passive hyperemia, massage, massage of the hand in a mercury bath, ionization and radio-active applications.

131. **Medicinal Treatment of Tabes and General Paralysis.**—Donath remarks that the recently acquired knowledge that [illegible] are actual syphilitic processes

tabes and
points the
not retrog
varsan or
may be in

be and generally are aggravated by a kind of Herxheimer reaction, but if the patients are warned of this beforehand and told that the treatment will rouse up the disease, they bear with equanimity the aggravation and in a day or so the symptoms subside and great improvement becomes manifest. In a recent case a tabetic had suffered so long and intensely from gastric crises that an opening had been made into the intestine to permit him to be fed. As the crises still persisted, the Förster operation was contemplated. Donath was then consulted and he gave him neosalvarsan, about 2.55 gm. in four doses in the course of a month. After each infusion a severe gastric crisis followed for several hours but it then subsided, and as the patient could eat he gained rapidly in weight and strength and for nearly three months to date has had no further crises. Another patient with gummatous meningomyelitis, scarcely able to walk, had complete paraplegia develop the day after an intravenous injection of 0.3 gm. neosalvarsan. The paraplegia improved after a few days and by the end of the second week the dose could be repeated and the improvement has been progressive since; the patient can now walk normally. Donath warns that certain patients are unable to bear mercury, and this has to be dropped. He states that he has had no mishap in the more than 3.000 infusions he has made. The untoward by-effects reported in the early days of the salvarsan era were due to lack of care in regard to the smallness of the first doses, strict asepsis, mastery of the technic and exclusion from this treatment of persons with much degenerated important organs. He adds that electricity, hydrotherapy, massage and Frenkel's method of reeducating the muscles are seldom needed when the antisyphilis treatment can be vigorously applied, but they may prove useful when this is impossible.

132. **Whooping-Cough.**—Ochsenius was impressed with the fact that whooping-cough in its early stages presents merely the picture of infection of the upper air passages, pharyngitis with or without coryza. Aiming to prevent the spread of the infection downward, he paints the throat with a 2 per cent. solution of silver nitrate and in eighty-four of the ninety-five children to whom he has applied this measure in a thorough fashion, the effect was most excellent. The caustic action not only prevents secretion of mucus and thus wards off coughing spasms from irritation, but it has a most valuable effect on the child by suggestion. In the few cases in which this treatment seemed to fail, the children were all types of the exudative diathesis. He makes the application on alternate days, for infants every day at first, plus hydrogen dioxid. The result of the treatment was that by the end of the week the number of spasms was about the same but they were much less severe and there was much less secretion, and gradually the spasms became merely an ordinary cough.

149 Progressive Dystrophy of the Muscles; Death from Paralysis of the Diaphragm. C. Braunwarth.

148. **Roentgen Examination of the Stomach.**—Schüller writes from the hospital at Düsseldorf that Roentgen examination of the stomach in 1,200 cases has confirmed the great value of this means of investigation in malignant disease, but that it is of little use for diagnosis of gastric ulcer. It shows up an indurated, perforated ulcer, but this type is rare; it also shows the sequels of an ulcer, but to date, he declares, the Roentgen rays have not helped at all in the diagnosis of a recent ulcer and in the overwhelming majority of cases of chronic ulcer. With cancer, however, it instructively supplements the clinical examination and the history of the case. In all his experience the Roentgen findings were never normal in a case with a history of stomach trouble for some time and actual cancer. On the other hand, the trouble never proved to be cancer when with the history of stomach trouble for some time roentgenoscopy showed apparently normal conditions in the stomach. Absolute certainty can be expected only with positive findings, as an incipient cancer may give no sign of its presence. He lays the principal stress on roentgenoscopy, showing the peristalsis and movability of the stomach, viewing it from different points. Roentgenograms are far less instructive. He adds that beginning cancerous degeneration of an old ulcer seldom shows conclusively on Roentgen examination. With this exception, normal findings enable malignant disease to be excluded and the patient reassured. When the ordinary means of investigation are supplemented by roentgenoscopy, we get as complete and accurate an estimate of conditions in the stomach as was attainable formerly only by an exploratory laparotomy. The various points liable to prove misleading are discussed in detail with about a hundred small skiagrams to illustrate the various instructive types encountered in bismuth work.

152 Operation for Congenital Diverticulum in the Bladder. Kreuter.

150. **Differential Pressure by Way of the Nose.**—Zaaijer reports from Korteweg's surgical clinic at Leyden a remarkably simple and effectual technic for maintaining positive pressure in the lungs during operations on the esophagus. The large apparatus for differential pressure are complicated and expensive, and the Meltzer-Auer technic for intracheal insufflation is sometimes difficult to realize. He has experimented only on dogs, but he found his method so practical and effectual that he thinks it is applicable for the clinic. A rubber tube was introduced for a few centimeters in each nostril, the size of the tube such that it fits firmly in place. It is easily introduced over a catheter. By connecting these tubes with the oxygen tank and introducing a water safety-valve between the tank and the nostril, the lungs can be kept pumped full of air even with the chest open; the animal continues to breathe tranquilly. Even when the mouth is open, the breathing proceeds tranquilly, only a little more oxygen is required. He thus kept the animal for five minutes in tranquil general anesthesia with free access of air to each side of the chest, with his mouth open and with a catheter introduced into the esophagus. He found in tests on himself and on an anesthetized patient that respiration proceeded practically normally with open mouth. He did not force the positive pressure above 6 cm. water. The pharynx closes up, the intrapharyngeal pressure forcing the soft palate downward and the epiglottis forward. Only intermittently was it possible for air to escape through some narrow slit. He adds that the oxygen-chloroform mixture may be passed through warm water as with the Meltzer technic.

151. **Liquid Paraffin as Dressing for Wounds.**—Chrysospathes found paraffin oil an effectual dressing for sores of all kinds, and reports here that he applied it in treatment of wounds in the Balkan War in 920 cases and the wound healed over in a remarkably short time with a few rare exceptions. Even gaping wounds with exposed bones began to heal at once. The results were even better when he added about 2 per cent. iodoform with particularly severe suppuration. If the gauze sticks, it can be detached by pouring a little more of the oil on it or hydrogen dioxid. He expatiates on the advantages of this simple method of treatment, which does away with all salve and time-stealing procedures. In some of his cases the temperature dropped to normal each time after application of the paraffin, but rose again when the oil was suspended. He has been using this method for some years, having found it so effectual for sterilizing catheters and healing bed-sores.

154 *Extraperitoneal Cesarean Section and Pubiotomy. (Extraperitonealer Kaiserschnitt und Beckenspaltung.) W. Weibel.

153. **Radiotherapy of Cancer of the Uterine Cervix.**—Sigwart gives some cystoscope views of the interior of the bladder taken before and after Roentgen treatment of a cancer in the uterine cervix. They show the remarkable retrogression of the bladder changes as the uterine growth subsided under the Roentgen treatment.

154. **Extraperitoneal Cesarean Section and Pubiotomy.**—Weibel states that extraperitoneal cesarean section has been applied in sixty-seven cases during the last five years at Wertheim's clinic at Vienna; during this period pubiotomy has been done thirty-nine times and symphyseotomy not once. In the sixty-seven extraperitoneal cesarean sections, all but two of the children were delivered alive; in one case the mother had become very much asphyxiated during the operation and in the other case the fetal heart sound had grown abnormally weak before any intervention. The mortality in the sixty-seven cases was 3 per cent. and none in the last series of fifty-two women succumbed. One of the thirty-nine women requiring pubiotomy died from thrombophlebitis, twenty-five days after the operation. He thinks that the mortality of 8 per cent. among the children for both opera-

tions is encouragingly low. The 3 per cent. mortality among the mothers occurred while the method was still in its tentative stage.

156 Quantitative Determination of Indican in the Urine. (Harnindikanbestimmung.) D. Natonek.

155. **Atrophy of the Intestinal Mucosa in Pernicious Anemia.**—Lippmann has been investigating the normal relations between the apparent and the real functional capacity of the stomach. He describes the method by which he determined the comparative weight of the musculature and the stomach and the intestine. In a typical case of pernicious anemia he found that the proportion between the mucosa and the musculature in the small intestine was as 100 to 198; for the large intestine as 100 and 403. These findings exclude the assumption that atrophy of the mucosa is a constant accompaniment of pernicious anemia.

161 Epidemic of Undulant (Malta) Fever in Italy. O. Golini.

158. **Infantile Scorbutus.**—Spolverini reports three cases to show the difficulty of differentiating the true cause for the disturbances in the incomplete forms of scorbutus in infants. There was no swelling of the gums or thickening of the shafts of the long bones in his cases to suggest Barlow's disease; the children merely grew paler and restless, whining and pleading to be taken up and carried, tiring easily, sweating freely, particularly in the head and face. There was nothing characteristic about the symptoms, but the weakness and anemia persisted uninfluenced by ordinary means. There was no spontaneous pain, but the children kept very quiet, with the legs drawn up, to avoid the pain from movements. One of the children was about 2 years, the others 10 or 19 months old. The differentiation in such cases from hip-joint or spinal disease, acute rachitis, neuritis, etc., is by exclusion and by the prompt benefit from change of diet.

167 *Stain for Tubercle Bacilli. (Metodo rapidissimo per la colorazione del bacillo tubercolare.) N. Mori.

162. **Amputation of the Breast.**—Tansini's technic for radical removal of cancer of the breast was described in THE JOURNAL, March 23, 1912, p. 899. He thinks it should be given the preference whenever a radical operation is possible as it does away with the possibility of recurrence in the skin, which his experience previously has shown to be a most common type of recurrence. A few months or years after the operation with other technics, a cancer lump appears in the skin, while recurrence in muscle or lymph-node is much less frequent, at least in Italy, he says. Others besides himself have commented on this. Other surgeons regard the skin as of less importance than muscle and lymph-nodes when it is a question of recurrence and they are liable to pay dearly for this confidence in the skin. After Tansini has extensively removed the skin he covers the vast defect left by twisting a large flap around from the back, the farthest possible from the skin near the site of the cancer. His method is thus not essentially a plastic operation, but he has to do an extensive plastic operation to conclude his thorough removal of the cancer and tissues liable to recurrence. His method has the incidental advantage that it does away with the linear scar in the axilla which is liable to shrivel and interfere with the use of the arm.

165. **Azurophil Lymphocytes in Infectious Diseases.**—Mondolfo found granulations taking azure stain in the lymphatic cells in all the infectious diseases studied but not with any degree of constancy or intensity of staining. On the other hand, they proved invariably constant and strongly azurophil in measles—possibly a fact of diagnostic importance.

166. **Benzol in Leukemia.**—In the four cases of leukemia reported, little if any benefit was realized from the benzol.

167. **Improved Stain for Tubercle Bacilli.**—Mori regards the technic he describes as the best yet proposed, not only for its rapid action and reliability, but for the beauty of the results. It is a modification of Ziehl's first method, differing by the formula of the fuchsin stain, and by the fact that all can be used cold, and that no sediment develops on standing. The carbol-fuchsin solution is made with 0.5 gm. fuchsin, 10 c.c. absolute alcohol, 2.5 gm. phenol and 100 c.c. distilled water. The fuchsin is dissolved in the alcohol, the phenol is then added, and then the water is stirred in a little at a time, and the mixture is then set aside for twenty-four hours and then filtered. Differentiation is done with a 1 per cent. solution of sulphuric acid, and the contrast staining with a 1 to 4,000 solution of methylene blue. Each fluid is applied in turn for ten or fifteen minutes, washing in water between.

# TREATMENT OF PNEUMONIA WITH PARTIALLY AUTOLYZED PNEUMOCOCCI *

E. C. ROSENOW, M.D.
AND
L. HEKTOEN, M.D.
CHICAGO

Rosenow has shown that when virulent pneumococci are suspended in physiologic salt solution the substance or substances on which their resistance to phagocytosis and virulence depend pass into solution.[1] The soluble part or "virulin" at a certain stage of autolysis is highly toxic and has little immunizing action, while the insoluble remnants have well-marked antigenic properties and practically no toxic effects. The soluble toxic part has been found to interfere with the formation of antibodies following injections of the non-toxic insoluble remnants. The protective value against experimental pneumococcus infections of detoxicated pneumococci has been found to be greater than that of heat-killed pneumococci.[2] For these reasons it seemed advisable to determine, if possible, whether or not the injection of virulent pneumococci, from which the readily soluble and toxic parts have been removed, would have any influence on the course and death-rate of lobar pneumonia.

## PREPARATION OF ANTIGENS

The antigens or vaccines used during the winter of 1911, eight in all, were prepared from twenty-four-hour cultures of highly virulent pneumococci grown chiefly in ascites-dextrose broth. The broth was prepared from meat infusion, rendered sugar free, and then 0.2 per cent. dextrose was added and ascites fluid in the proportion of one part in ten. After centrifugation the pneumococci were suspended in 0.5 per cent. phenol in sodium chlorid solution and placed at 37 C. (98.6 F.) for twenty-four hours. This was repeated once or twice, until practically all the organisms had become Gram-negative and eosinophilous. Three of the antigens were prepared in the same way from the washed pneumococci which had grown in the peritoneal cavity of guinea-pigs. The antigens used during 1912 and 1913 were prepared from a large number of strains of highly virulent pneumococci which had grown both in the peritoneal cavity of guinea-pigs and in ascites-dextrose broth. The growth equivalent to that of approximately 150 c.c. of broth was suspended in 30 c.c. sodium chlorid solution at 37 C. under ether. In the case of the antigen used in 1912 the cocci were removed by centrifugation at the end of forty-eight hours and resuspended in sodium chlorid solution under ether. This was repeated twice. The disintegration was then marked and all the cocci had become Gram-negative. The antigen used during the winter of 1913 was prepared by suspending the pneumococci in sodium chlorid solution under ether at 37 C. until 7 c.c. of the suspension were no longer toxic for guinea-pigs when injected intravenously; that is, for about seventy-two hours. The organisms at this time had nearly all become Gram-negative. The sterility of the final product was determined by making both aerobic and anaerobic cultures on blood-agar. Some care must be exercised not to carry the process too far, because then all antigenic powers may be lost; experiments indicate that the best time to interrupt the lysis is when almost all the cocci have lost their affinity for the Gram stain. Standardized suspensions are used from the beginning of the extraction, and the final suspension represents about 20 billion pneumococci per cubic centimeter. This is kept in the ice-chest.

The dose used during the winter of 1911 varied from 10 to 20 billion. The injections were given subcutaneously daily until the temperature reached normal. During the second period, 1912, only one injection of approximately 20 billion was given as soon as the diagnosis was established, while during the past winter from 10 to 15 billion were given daily until the temperature reached normal. Only slight tenderness follows the injection and there is little local and no general reaction noticeable.

## THE TREATMENT OF CASES

The cases treated may be considered in three classes: the cases treated outside of the hospital, the uncontrolled cases in the hospital and those controlled by alternate untreated cases.

The results in the thirty cases occurring in the practice of physicians outside of the hospital were better than those obtained in the more unfavorable cases in the hospital. Of the 30 patients, three died. One of these showed a large number of influenza bacilli in the sputum, together with pneumococci and streptococci; the second patient had a high grade of emphysema, due to a bronchial asthma of long standing, and the third death occurred in an alcoholic aged 58 who had a chronic myocarditis. Injections were begun in the fatal cases on the fifth, second and fifth day, respectively; in the patients who recovered, on the first or second day in seven, on the third day in eight, on the fourth day in five and on the fifth, sixth and seventh days in six; while in four cases the exact time of onset could not be ascertained. The ages ranged from 19 to 58 years. The results as determined by observation at the bedside when the treatment was begun within forty-eight hours of the onset often

---

* From the Memorial Institute for Infectious Diseases, Chicago.

[1] Rosenow, E. C.: Human Pneumococcal Opsonin and Antiopsonic Substance in Virulent Pneumococci, Jour. Infect. Dis., 1907, iv, 285; abstr., THE JOURNAL A. M. A., July 6, 1907, p. 87. Tchistovitch and Yourevitch (Ann. de l'Inst. Pasteur, 1908, xxii, 611) made the same discovery.

[2] See preliminary note by Rosenow, E. C.: Autolysis of Pneumococci and the Effect of the Injection of Autolyzed Pneumococci, THE JOURNAL A. M. A., June 11, 1910, p. 1943; Immunization in [illegible], Sept. 7, 1912, p. 795; Mechanism of Intox- [illegible] Anaphylaxis and in Pneumococcus Infec- [illegible] ernat. Cong. Hyg. and Demog., 1912, ii, 338.

seemed striking: there was usually a rise of about a degree in temperature in a few hours, then the temperature would usually drop markedly, to remain one or two degrees lower the following day, and if now the injection was repeated, a normal temperature was often reached in three, four or five days after the onset. When the injections were given in three or four days after the onset the beneficial effect was less evident, while if begun still later there was no apparent improvement. Harmful effects have not been observed in any of the cases.

The second group, consisting of thirty-five cases, occurred in the Cook County Hospital during November and December, 1910. They were treated in the same manner as the cases just mentioned. Nine of these patients died, a death-rate of 25.7 per cent. The injections in the fatal cases were begun on the second day in only one case, on the third day in two, and in the remaining on the fourth, fifth and sixth days. One of these cases was found to be streptococcus pneumonia, in the other pneumonia developed during puerperal sepsis, and one patient had delirium tremens. Three others were bad alcoholics. The treatment in the cases with recovery was begun on the second day in two, on the third in three, on the fourth in three, and on the fifth, sixth, seventh and eighth days in the rest. The ages in this group ranged between 18 and 70 years.

We come now to the consideration of the third and largest group. The good effect of the early injections often seemed convincing, but because pneumonia is so variable in its course some sort of control is desirable. In order to do this most effectively we used the statistical method. Every second pneumonia patient in the order admitted to the Cook County Hospital of Chicago during January, February and March of 1911, 1912 and 1913, the height of each pneumonia season, was injected subcutaneously with detoxicated pneumococci at the same time as he received the usual routine treatment given to all patients with pneumonia, which was not modified in any way whatsoever. There was no selection practiced at all—every second pneumonia patient was injected, the uninjected serving as the control group. We are deeply indebted to the physicians of the hospital for their willing cooperation and encouragement. Altogether there are 294 cases for consideration in this group, 146 receiving the injections and 148 constituting the controls. Of the control group fifty-six died, a death-rate of 37.8 per cent. Of the injected group thirty-four died, a death-rate of 23.3 per cent., a total lowering of the death-rate of 14.5 per cent. in the injected group.

TABLE 1.—DEATH-RATE IN THE TREATED AND UNTREATED PNEUMONIA CASES BY YEARS

| Year | Treated | | | Untreated | | |
|---|---|---|---|---|---|---|
| | Total No. | No. Died | Death-Rate | Total No. | No. Died | Death-Rate |
| 1911 ........ | 51 | 16 | 31% | 50 | 25 | 50% |
| 1912 ........ | 46 | 11 | 24% | 48 | 15 | 31.2% |
| 1913 ........ | 49 | 7 | 14.3% | 50 | 16 | 32% |

Table 1 shows that the mortality-rate was lower in the injected than in the uninjected or control cases during each of the three pneumonia seasons. The unfavorable class of cases that we are dealing with is well illustrated by the very high death-rate of the control cases. It should be said at this time that the death-rate from pneumonia in Cook County Hospital is always very high because most of the pneumonia patients are of the least favorably situated class, hygienically and economically, of the whole adult male population of Chicago, many of them using alcohol excessively.

In Table 2 the death-rate is given by decennial periods. It shows a consistently lower death-rate in the injected cases than in the uninjected cases in each period except between the ages of 61 and 70 years. Here the mortality is slightly higher in the treated cases; but only four were treated with two deaths, whereas in the controls there were eleven cases with five deaths.

TABLE 2.—ANALYSIS OF THE RESULTS BY AGE-PERIODS

| Decennial Periods | Treated | | | Untreated | | |
|---|---|---|---|---|---|---|
| | Total No. | No. Died | Death-Rate | Total No. | No. Died | Death-Rate |
| 1-20 | 21 | 0 | 0 % | 17 | 2 | 11.4 % |
| 21-30 | 39 | 7 | 18 % | 36 | 8 | 22.2 % |
| 31-40 | 43 | 11 | 25.5% | 34 | 14 | 41.1 % |
| 41-50 | 25 | 8 | 32 % | 32 | 14 | 43.7 % |
| 51-60 | 14 | 6 | 42.8% | 18 | 13 | 72 % |
| 61-70 | 4 | 2 | 50 % | 11 | 5 | 45.45% |
| | 146 | 34 | 23.3% | 148 | 56 | 37.8 % |

The incidence of complications and sequelae seems about the same in both groups, and the attack terminated by crisis of those that recovered in 71 per cent. of the injected and in 65 per cent. of the uninjected group. There is a tendency to earlier crisis in the injected group, especially in the cases in which there was a chance to begin the injections early. Thus during 1911 and 1913 when this point was studied, the injections were begun on the first or second day in all but two of the twenty-one cases in which crisis occurred on the sixth day or earlier.

Further analysis of the cases shows that the average age of the injected patients is 34 years while that for the uninjected patients is 36 years. The average age of the injected patients who died is 42.3 years, that of the uninjected patients who died is 42.9.

According to the facts obtained there were seventy-two bad alcoholics in the uninjected group and of these twenty died; there were seventy-three bad alcoholics in the injected group and of these twenty-six died.

The average duration of illness before entrance to the hospital in the control group is 4.3 days; of the control fatal cases 4.4 days; of the injected cases 3.9 days, and of the injected fatal cases 4.3 days. The first injection in nearly all cases was given the day after admission. This makes the average time of the first injection about the fifth day of the disease—necessarily a disadvantage in any form of treatment of pneumonia and particularly for the one under consideration.

### CONCLUSIONS

In view of the fact that the mortality is consistently lower in the injected cases each year, that the average time of the first injection was late (approximately the fifth day), and that the type of cases treated is of the worst kind, nearly one-half of the patients being bad alcoholics, the conclusion that this method of treatment of pneumonia is of value seems warranted.

The results obtained in the series outside of the hospital, in which the injections were begun earlier, indicate that by the early administration of the antigen better results can be secured. Further observations require the cooperation of physicians who are in position to give the injections at the earliest moment.[3]

[3] *The antigen or vaccine is kept on hand and it will be sent free on application to physicians who are willing to send us records of the cases.*

# ENTERICOID FEVER—FEBRIS ENTERICOIDES *

DAVID RIESMAN, M.D.
PHILADELPHIA

During the last few years I have seen a number of cases of continued fever that resembled typhoid fever but did not give the usual laboratory tests nor did they present all of the characteristic clinical features of that disease. In their symptomatology they did not, however, depart from the text-book description more than many well authenticated cases of typhoid fever. I am sure that every physician in active practice sees cases of fever that impress him in the beginning as typhoid, and if he commits himself to this diagnosis he is often much embarrassed to find that the duration is too short for it to be typhoid fever or that the case does not give the laboratory reactions of that disease. I am, of course, not referring to certain widely different infections that may assume a typhoid type, such as ulcerative endocarditis, miliary and caseous tuberculosis, meningitis, etc.

One of these typhoid-like infections has already been established as a clinical entity, namely paratyphoid fever. But it has seemed to me from observation and a perusal of some recent literature that in addition to paratyphoid fever there are other febrile affections that at present are either included under the head of typhoid fever or are as yet "without a local habitation and a name." The recognition of paratyphoid fever has come as a welcome escape from a perplexing dilemma, for it helps to explain a number of otherwise puzzling facts. It explains the occurrence of second attacks of typhoid fever. Most of the literature on this subject antedates the discovery of the paratyphoid bacillus. Inasmuch as typhoid fever does not protect against paratyphoid fever, a person may have the two diseases at different times. The observer not familiar with the facts and not making the differential clinical tests takes it for granted that the two attacks are both typhoid fever. I would, of course, not deny the possibility of typhoid recurrence, but I believe that the newer studies will show its great infrequency. Another disturbing factor for which we now have a fairly satisfactory explanation is the observation that a goodly proportion of persons vaccinated against typhoid fever later developed a typhoid-like infection. Without careful laboratory study the inference would have been drawn that vaccination against typhoid was not as completely protective as its advocates had claimed. But when it is found that the disease attacking the vaccinated persons is not typhoid but paratyphoid fever, then our confidence in vaccination returns, though it is chastened by the thought that its protection is too specific and too limited. Hence we must approve the suggestion of Colonel Firth[1] that vaccination in the future should be done both against typhoid and against paratyphoid fever. I may add, however, that I have seen two cases in which, despite antityphoid vaccination made *secundum artem*, a febrile disease developed three months later which by the ordinary clinical and laboratory tests seemed to be true typhoid. One of the cases[2] ended fatally and at necropsy typhoid ulcers were found.

Through an unusual coincidence I had under observation during the past summer (1912) four cases of continued fever that, while resembling typhoid fever most closely, could not with justice be so designated.

CASE 1.—S. M., a married woman, aged 40, a native of England, residence Telford, Pa., was admitted to the Jewish Hospital on Aug. 17, 1912, complaining of headache from which she had been suffering for three weeks. In the beginning she had had chills for two days and a little nausea. Twelve years before she had had an attack of typhoid fever and had been treated for it in a hospital in Philadelphia. Up to three weeks before admission she had been obtaining her drinking-water from a well on the farm, but changed then to town water because the well-water was beginning to have an offensive odor. Her temperature was somewhat irregular, ranging between 99 and 102 F. with occasional drops to below normal. The fever persisted from her admission on August 17 until September 16, exactly thirty days, and as she had been ill two weeks prior to admission her disease lasted altogether six weeks. Throughout her stay in the hospital the patient made no complaint. She had no diarrhea, no delirium, no rose spots, or palpable spleen. The Widal and diazo reactions were negative. The leukocytes were 5,400; the red cells 4,320,000; the hemoglobin 75 per cent. Recovery was complete.

CASE 2.—G. H., a lawyer, single, aged 41, brother of a physician, entered the Jewish Hospital Sept. 5, 1912, having been ill a week. Nine years previously he had had an attack of typhoid fever lasting three months. Physical examination was entirely negative. There was no enlargement of the spleen, no roseola. The leukocytes numbered 7,400. The Widal test and blood-culture gave negative results. The temperature remained elevated for ten days after admission, reaching 102 F. as its highest. Decline was by lysis.

CASE 3.—M. R., a single woman, aged 57, a seamstress by occupation, was admitted to the Jewish Hospital on Sept. 7, 1912, with a history of having been ill five weeks with fever, diarrhea and occasional vomiting. In July, 1911, she had, according to her statement, an attack of typhoid fever. The house in which she had lived had very bad drainage. Physical examination showed a few doubtful rose spots; the spleen was not demonstrably enlarged; at both pulmonary bases fine crackling râles could be heard. A curious feature was the presence of a pulse of the water-hammer type without any manifest aortic insufficiency. The temperature oscillated considerably, rarely sinking to normal and reaching as its highest point 104 F. It declined gradually and became normal on September 20, exactly two weeks after admission. If these two weeks are added to the five she was ill before coming to the hospital, there is a total duration of seven weeks. The blood showed 5,400 leukocytes. The Widal reaction was negative on September 9 and positive on September 29. The blood-culture was negative and a culture of the feces showed the colon bacillus and a staphylococcus. A culture of the urine was made but unfortunately became contaminated.

CASE 4.—M. J., aged 23, is the wife of a surgeon in the United State Navy. Her medical history is interesting. Wherever she has lived, and she has lived in many places, she seems to have fallen a victim to the indigenous disease. At the age of 8, while residing at Fort Myer, she had an attack of dysentery, another while in Cuba, and a third while in the Philippine Islands. In the last place she also had two attacks of dengue. In January of this year (1912) she received a series of three injections of typhoid vaccine.[3] In July she had an operation for dilatation and curettement. She was taken ill on August 1 with general malaise and headache. On August 8 she got a thorough wetting which was followed by headache and severe pains throughout the body. She entered the university hospital on August 15, with a temperature of 104 F. When I saw her for the first time, she was bright and alert, but preferred to keep her eyes covered with a folded handkerchief. Her face was flushed and around the eyes there was a bright ring of erythema. Heart and lungs presented nothing abnormal. The spleen was not palpable. Over the legs there were numerous crusts, the remains of an eruption of dermatitis herpetiformis, from attacks of which the patient had suffered for many years. There was considerable cough with scanty expectoration, in which some micro-organisms in chains and short encapsulated Gram-negative and also Gram-positive diplococci were found. Tubercle bacilli were not present. The leukocytes were 7,700, with a normal differential count. The urine gave doubtful diazo reaction. The Widal test was negative in the beginning, doubtful on August 19, negative on August 29 and on September 2. On September 2 the patient had two chills a half-hour apart without sweats, headache or nausea. The next day the leukocytes were 16,600. Blood-culture gave negative results and two examinations of the stools for typhoid bacilli were likewise negative, only the *Bacillus pyocyaneus* and the colon bacillus being found. All tests for the paratyphoid organism were also negative. Eighteen days after admission, or nearly five weeks after the beginning of the illness, a few rose-colored spots appeared on the abdomen. The temperature throughout was somewhat irregular—from 101 to 104 F. during the first week, afterward between 99 and 101 F., then again between 101 and 104 F. It reached normal September 14, exactly thirty days after the patient's entrance into the hospital.

* Read before the Section in Medicine of the College of Physicians of Philadelphia, Oct. 28, 1912.

[1] Firth: Jour. Roy. Army Med. Corps, 1912, No. 19, p. 157.

[2] Since the foregoing was written the organism isolated from the fatal case has been carefully studied by Dr. K. F. Meyer, of the State Livestock Sanitary Board, with the *most* interesting result that, though belonging to the typhoid group, it proved to be neither the ordinary typhoid nor the paratyphoid bacillus.

[3] According to Colonel Firth, Major Russell, Spooner, and others, the antityphoid vaccination protects for at least thirty months.

## REMARKS

I think I can say quite definitely that the disease in these four patients was not typhoid fever, although for want of a better name it was so entered in the hospital records. As to the possibility of its having been paratyphoid fever, there is no clear evidence either one way or the other in the first three, while in the fourth all the known tests for paratyphoid fever proved negative. The etiology thus remains obscure; and so it will remain in many other cases of like nature until we have more accurate diagnostic tests. Progress will be made in this confused field as soon as the fact is recognized that there are organisms allied to the typhoid bacillus that are capable of producing typhoid-like febrile diseases. By means of cultural and serologic tests it is now comparatively easy to separate from typhoid fever a disease formerly confounded with it called paratyphoid fever, but further refinement of our biologic methods will, I am sure, reveal still other types of infection. Even now it is possible to separate paratyphoid fever into two subvarieties, one due to the paratyphoid bacillus A, an organism closely allied to the true typhoid bacillus, and one due to the so-called paratyphoid bacillus B.[4]

The typhoid bacillus is almost exclusively a human parasite. This is also true of the *Bacillus paratyphosus* A. The paratyphoid bacillus B, on the other hand, has a wide distribution in the lower animals, especially in those serving for human food. While generally a harmless saprophyte, it may, like the human colon bacillus, become pathogenic under certain conditions, causing various forms of animal diseases. The meat of such animals may then in turn be harmful to man. I believe that this form of food infection is at the bottom of many obscure cases that at the present time either cannot be classified or are wrongly designated as typhoid fever.

Two principal types of organisms have been found as the cause of food poisoning—the Gärtner type (type of the *Bacillus enteritidis Gärtner*) and the paratyphoid B type. Both of these are represented in nature by many subspecies. They are found in the flesh of diseased animals, but some, especially the paratyphoid B group, also in animals that are apparently well. Moreover, the meat of healthy animals may in the slaughter-house or in the butcher-shop become contaminated through contact with parts of diseased animals. Among the meats used for food, veal seems to be the chief purveyor of infection, but many meat products, poultry—especially goose—fish, lobster, oysters, milk, eggs and cheese may carry the germs.[5]

Much interest attaches to the *Bacillus suipestifer*, a common pathogenic parasite of hogs. It is erroneously called the bacillus of hog cholera; the latter disease is due to an invisible virus with which the bacillus seems always to be closely associated. On account of its ubiquity, the *Bacillus suipestifer* is an important organism, though the exact rôle it plays in human pathology, if it plays any, is still unknown. Morphologically, it is indistinguishable from the paratyphoid bacillus.

Another interesting though little understood point in the epidemiology of this group of infections is the existence of typhoid-like organisms in animals not used for slaughter, such as mice, rats, parrots, canary birds, rabbits and guinea-pigs. Loeffler, in a very fatal epizootic among mice characterized by gastro-enteritis, isolated an organism, the *Bacillus typhi murium*, that is virtually identical with the paratyphoid organism. Nocard, in parrots dying of an epidemic enteritis, found the so-called psittacosis bacillus, which likewise has nearly all the characteristics of the paratyphoid bacillus B. Cases of transmission[6] of the psittacosis bacillus from parrots to human beings have been reported from France and Germany. Another organism not distinguishable from the paratyphoid bacillus was found by Mori in cats dying of acute enteritis. Since animal parasites may easily be conveyed from the lower animals to man, it is not surprising that bacterial infection from one to the other, even when the animals are not used for slaughter, also readily occurs. It is probable that infection is brought about more often through meat and other animal food products than through the medium of domestic pets and rodents. In obscure cases, however, all those possible sources should be taken into consideration.

The symptoms of infection naturally vary widely depending on the virulence of the organism and the susceptibility of the host. Some of the toxins of the paratyphoid group are exceedingly powerful, causing a prompt and violent toxic gastro-enteritis. As they are thermostabile the cooking process does not lessen their toxicity. Many cases of so-called ptomain poisoning and cholera morbus probably have such an origin.

Instead of causing a pronounced local inflammation, the organisms may bring about a general disease in which the local manifestations are but of slight moment. This is the typhoid type of the infection and the one that causes most of the diagnostic difficulties. The disease may last a short time or may be prolonged for weeks. Many and varied are the diagnoses made in protracted cases. Relapses are rarer in paratyphoid forms than in true typhoid fever.

I thought it would be convenient, even though it might not help to clarify the subject, if there were a term to designate all the diseases that resemble but are not true typhoid fever and that are due to micro-organisms of the large paratyphoid family. As the word "typhoid-oid," though expressive is not euphonious, I avail myself of the suggestion made by Dr. H. A. Hare in discussing this paper and propose the name "entericoid" fevers. Up to the present paratyphoid is the best known of the entericoid fevers. In time, as I have intimated, we shall learn to distinguish others—by agglutination and absorption tests,[7] by cultural methods, particularly culture on sugar mediums, and by animal inoculation.

---

[4] For unknown reasons the majority of cases of paratyphoid in Germany seem to be due to the paratyphosus B, while in this country and in India the paratyphosus A plays the major rôle.

[5] It may not be amiss to say that sausage-poisoning is due to a wholly different cause, namely, to an anaerobic bacterium—the *Bacillus botulinus*. The symptoms produced by this organism resemble those of atropin-poisoning.

[6] Drewes reports an interesting case in which a woman who had bought a parrot fell ill of a typhoid-like affection. On investigation it was discovered that the saleswoman from whom she had purchased the parrot was a paratyphoid carrier.

The knowledge that there are many other modes of infection aside from those known to convey typhoid fever —that meat and meat products, poultry, eggs, cheese and other articles of food may transmit pathogenic species of the paratyphoid group, and that mice and rats, cats and birds may be carriers of similar organisms, should stimulate us to trace the source of infection in every enigmatic case.

### CONCLUSIONS

1. The term "typhoid fever" as commonly used by physicians includes more than one variety of disease.
2. Only that in which the characteristic serologic and cultural tests for the typhoid bacillus are obtained should be called typhoid fever.
3. To the others, which clinically may resemble typhoid very closely, the term "entericoid fever" may be applied.
4. The entericoid fevers are due to different strains of organisms of the paratyphoid group and to others morphologically similar (Gärtner's *Bacillus enteritidis*, etc.).
5. The source of infection is chiefly food derived from unhealthy animals.
6. Food (including drink) may become contaminated through contact with diseased meat, through rodents, birds, or through the discharges of carriers, etc.
7. So-called second attacks of typhoid fever are probably entericoid (paratyphoid) fever, provided of course the first was genuine typhoid fever.
8. In all cases of typhoid-like character careful search should be made for the source of infection, and blood-cultures and other tests for the determination of the infecting agent.
9. By combined clinical and laboratory investigations it should eventually be possible to distinguish, according to their specific etiology, the various entericoid diseases now grouped together.

1715 Spruce Street.

---

[7] The absorption test was proposed by Castellani and is as follows: If it is intended to determine whether a given specimen of blood-serum contains agglutinins, for example, for the *Bacillus paratyphosus* B, the group agglutinins are first removed by mixing the serum with cultures of the typhoid bacillus, the *Bacillus paratyphosus* A, etc. Any agglutinins of these organisms will be absorbed, leaving that for paratyphosus B intact if it is present. It should be borne in mind that the paratyphoid produces very weak agglutinins, so that a negative Widal reaction for it has less value than in the case of typhoid fever.

**Individual Health Depends on Community Health.**—The health of the community depends on the health of the citizens, but the health of each individual also depends in some measure, often in large measure, on that of the other members of the community. Health of the individual is therefore a condition that, generally speaking, can be maintained only by a combination of individual and community effort, and its importance is such that in the activities of the city and of the state it should hold a prominent place. The health of the community should be of greater concern than commercial prosperity, for it is essential to commercial prosperity. Necessary as are our courts, our fire and police departments, and our educational systems, the importance of the community's attention to the citizen's health is second to none.—John W. Trask, *Pub. Health Rep.*

# THE TREATMENT OF HEMOPTYSIS IN PULMONARY TUBERCULOSIS

NEWELL BLY BURNS, A.B., M.D.
First Assistant Physician, State Sanatorium
NORTH READING, MASS.

Hemoptysis of known pulmonary origin in tuberculosis is now treated at North Reading in a rather original manner. The plan in use was selected for its superiority after three years of gradual elimination of various forms of treatment.

Many methods commonly employed to cope with pulmonary hemorrhage were discarded after a fair trial on account of inefficiency and harmful sequelae. For instance, morphin, generally advocated and no doubt extensively used in the treatment of this complication, has fallen decidedly out of favor with us. The textbooks offer it for use by reason of the indication for the depression of respiratory activity, the allaying of excitement, and the suppression of cough. The idea is that all efforts should cooperate toward quieting the patient, but this seems to be without due regard for the alleviation of the trouble which causes the disturbance. Let one who prescribes morphin in such instances remain at the patient's bedside to observe the annoying symptoms which arise when the initial effect of the hypnotic begins to wear away, and he cannot help being impressed with the ultimately deleterious effect of that drug on the patient suffering from hemorrhage.

Our practice now is to discountenance the use of morphin and opium except in extreme cases, and to substitute therefor a treatment consisting mainly of depletive purgation. This plan seems most effective. Accordingly I feel that some description of its use and rationale merits wider circulation.

### METHOD OF TREATMENT

The patient who begins by coughing to expectorate clear blood from the lungs is immediately placed in a reclining position and is admonished to make no exertion. A curved basin is placed at the side of the face so that the patient may expectorate easily without lifting or turning his head. Any tight-fitting garments are released, but it is not well at this time to try to undress the patient.

Nitroglycerin, in 1/100 grain dose, is given subcutaneously as early as possible after the onset of the hemorrhage. Meanwhile an attendant prepares an ice-bag, also cracked ice to be taken by mouth. The ice-bag is placed at the patient's chest and if pain in any particular locality therein is complained of, the ice-bag is centered at that point. It often occurs that the patient has felt pain and soreness in a definite part of the lungs for some time prior to the hemorrhage, and at this point may be the focus of the bleeding. Hence the advisability of keeping the ice-bag over that spot.

It is well to encourage the patient and to tell him that very few patients ever die from hemoptysis and that by keeping quiet he may escape any serious consequences. A few assuring words from the physician and nurse will go a long way toward quieting the demoralization and panicky fear which many patients experience on the appearance of coughed-up blood. The patient should be told that he can help matters immensely by refraining from unnecessary coughing, by lying quietly, flat on his back without a pillow and by keeping as calm as his excited state of mind will permit.

Assuming that the patient is not suffering from extreme asthenia and is not affected with severe gastroenteritis or any ulceration along the digestive tract, a dose of magnesium sulphate from 1 to 2 ounces is administered within fifteen minutes to one-half hour after the appearance of the hemoptysis. Heroic suggestion and encouragement on the part of the physician are often necessary and is at the same time effective in securing the patient's cooperation both to swallow this medicine and to retain it. At the state sanatorium we have noted few cases in which the patient has lost the dose given, for, realizing his critical situation, he appears anxious to do his utmost to assimilate the salts; these may be more or less disguised by various substances and rendered pleasanter and easier to take.

It might be urged that this treatment is dangerous in that it might have a tendency to encourage nausea and distress, with vomiting and gagging at a most critical period, and hence occasion the release of more blood from the lungs. This has not been our experience and, furthermore, we have seen very few cases in which it might be suspected that retching, following the administration of the salts, was attributable to that cause. The beneficial results of this treatment are seen as soon as the purgative action begins. In about eight out of ten so treated hemorrhages have not recurred after the initial attack. No posthemorrhagic pneumonias ensue such as often complicate cases in which heavy doses of morphin are given and the patient feels brighter and more comfortable, in contrast to the depressing aftereffects of the morphin. Our use of magnesium sulphate depends on two clinical observations as well as other empiric reasons. In the first place, we have noted that many patients having hemorrhage at the time of onset of hemoptysis are suffering from severe constipation. The coincidence of the two conditions is so constant as to warrant the belief that a causative factor is represented, at least in some degree, by the sluggish bowel condition. A popular testimonial as to the genuine value of this tenet is seen in the fact that patients having a tendency toward hemorrhage who have been advised to take exceedingly good care to keep their bowels free are so impressed with the effectiveness of this practice in abating the frequency of the hemorrhages and streaked sputum that they learn enthusiastically to care for this matter themselves.

In the second place, a series of experimental cases was studied with regard to blood-pressure. Whenever it was necessary to relieve a patient's bowels which had not moved for some time, the blood-pressure was taken before relief and after free evacuation of the bowels by magnesium sulphate, when it was found that the blood-pressure dropped anywhere from 5 to 15 mm. (Tycos.). The blood-pressure in many cases in which there was persistent constipation was higher than is usual in tuberculous persons.

Finally we have noted the successful result secured by applying depletive purgation in cases in which hemorrhage occurs and, as in other empirical matters, this reason must be of the greatest importance.

In reviewing the records for one year, and even prior to that time, we have found it noted that a patient afflicted with a profuse pulmonary hemorrhage and treated by the usual method plus a moderate dose of morphin, would often have a recurrence of blood expectoration after the effect of the last dose of morphin was exhausted. With every hypodermic of morphin given the patient's condition would really become more serious, for although hemorrhages might not occur within the next hour or so, it was evident, nevertheless, that the reaction against the aggravated condition was only postponed. It is obvious that the prospect of reaction was intensified by each dose of morphin. Two cases in which the patients were subject to hemoptyses are herein reported and the result of the treatment we have suggested is noted.

## REPORT OF CASES

Case 1.—M. S., a girl, aged 16, formerly employed in a large biscuit factory, was admitted to the sanatorium, May 15, with moderately advanced pulmonary tuberculosis. The sputum was positive for tubercle bacilli on the first examination.

Examination of the chest revealed well-established infiltration of the upper lobe of the left lung with scattered moist râles. There were signs of beginning infiltration in the lower lobe as well as at the right apex. The nasopharynx and larynx showed incipient atrophic change but no bleeding points or ulcerations. The patient was poorly nourished but in fair strength.

The clinical course in this case was uneventful until June 8, when two severe hemoptyses occurred. Each time the regulation treatment given was nitroglycerin, grain 1/100, subcutaneously and application of an ice-bag, followed a few minutes later by a hypodermic of morphin, grain ¼, and atropin, grain 1/100, given to allay undue excitability, which was a marked characteristic of the patient. The bleeding continued and on the second day two larger hemorrhages occurred. There had been almost no evacuation of the bowels for about sixty hours, laxatives having no effect, and enemas producing very poor results. Some relief, however, was soon obtained and it was noted that streaked sputum was subsiding. For the next two weeks bloody sputum was observed daily. Incidentally, the constipation was very obstinate.

June 22 the patient suffered a second series of severe hemoptyses. It was learned that no bowel movement had occurred for forty-eight hours. The first hemorrhage was preceded for about nine hours by a sharp pain in the upper left chest. It should be stated that the intelligence of this patient was exceedingly meager, and therefore the amount of cooperation accorded the nurses and physicians correspondingly small.

The first hemorrhage of this date was at 5:30 a. m., and amounted to 2 ounces. In addition to the routine treatment of nitroglycerin administration, sodium phosphate ½ ounce was given, but without effecting purgation. A hypodermic of morphin and atropin of the usual dosage was also given. At noon a 4-ounce hemorrhage occurred; nitroglycerin 1/100 grain subcutaneously was again given, the application of ice-bags renewed, and morphin ⅛ grain hypodermically administered. One hour later a full dose of magnesium sulphate (1 ounce) was given, with no result. At 3:30 p. m., 5:30 p. m., and 9 p. m., hemorrhages recurred in amounts respectively 15, 6, and 6 ounces.

The pulse was thready and rapid, and as the patient had lost much blood the outlook was quite poor. Although the indications appeared to favor enteroclysis or hypodermoclysis, we determined to try to obtain depletive purgation for empiric reasons.

Accordingly magnesium sulphate, 3 ounces, was given in solution and the patient was encouraged to retain it; in less than an hour large watery movements began, and hemorrhage did not recur.

The following day the sputum was entirely clear of blood and the patient, although weak, was quite comfortable. The following week the patient rallied splendidly, escaping the posthemorrhagic pneumonia which so frequently complicates these situations, particularly when such frequent doses of morphin have been used.

No more hemoptyses occurred to Dec. 21, 1912, when the patient was discharged from the institution as a "quiescent" case.

The other example of this class of cases presents a record essentially the same except that this case was not only of advanced consumption but also of advanced alcoholism, a not infrequent complication.

CASE 2.—A plumber, aged 28, stated that he had first noticed the lung trouble four months prior to admission. He had had no hemorrhages; the sputum was positive for tubercle bacilli and the disease was far advanced in both lungs. He arrived at the hospital in an intoxicated condition and immediately began to oppose every sort of treatment prescribed, objecting to remaining in bed because it made him "nervous," "sicker," and protesting a variety of other alleged ill effects. The temperature ranged from 101 to 103 F., the pulse was rapid, the cough very distressing and marked tremors indicated the need of absolute rest. The patient became more unruly and almost unmanageable in the next few days and refused absolutely to cooperate in any way with those having his case in charge.

Blood soon began to appear in the daily specimens of sputum and as the patient was constipated, full doses of salts were ordered. The patient refused all medication. Hemorrhage precautions were ordered on November 1, but the patient was soon found walking about the ward, violating all orders and advice given for the prevention of hemoptysis.

November 2 a hemorrhage of 16 ounces occurred at noon; the patient refused to allow the nurse to give nitroglycerin subcutaneously and threw the ice-bag on the floor. There was a smaller recurrence of hemorrhage throughout the day and that night. November 3 a hemorrhage of 12 ounces occurred at 7:45 a. m., and blood was expectorated at intervals through the morning. The patient lost much blood and became quite weak and badly frightened. He was put on the danger list. He told the nurse and physician then that he would take anything. Two large doses of magnesium sulphate were given which effected the passage of several watery stools. There were no further hemorrhages and streaking in sputum subsided; the latter continued in slight amount, however, for six days. Active catharsis was kept up daily. The patient's hostile attitude changed to a better frame of mind. He is at present in the hospital, but has had no recurrence of hemorrhages.

The after-treatment, once the blood stops coming in any amount, is a matter of keeping the patient at rest, providing some liquid non-irritating nourishment and keeping the bowels clear. For at least twelve hours I keep the patient flat on the back without a pillow and insist on the use of the bedpan. The ice-bag is kept at the chest from two to three hours only and at the same time the rest of the body is kept as warm and as free from cramp as is consistent with absolute rest. It is perhaps better to remove the ice-bag from the chest early, and to replace it at intervals should necessity indicate. Much harm can be done by prolonging the application of cold to the thorax, for there comes a time when its contractile effect on the pulmonary blood-vessels is succeeded by a paralytic relaxation with ensuing trouble.

The tendency is to continue the ice-bag indefinitely, especially when it is left to the nurse, who regulates a matter of good treatment quantitatively. As long as the thorax is kept cold a warm water-bottle may be applied to the patient's stomach or feet, usually with considerable relief. The patient should be encouraged to look on the matter as cheerfully as possible, and a few hopeful words will often do a great deal toward dissipating worry and in adding to the patient's comfort. For medicine, sodium nitrate, 1 grain, may be given every three hours, with the hope that the blood-pressure will be reduced. This sometimes causes severe headache and its use is then discontinued. Empirically there seems to be no great benefit following its administration and its use is, therefore, only in accordance with the indication of a need to lower the blood-pressure.

Calcium sulphid in 1/6 grain tablets to the extent of three to six tablets three times daily are much in favor with us for the reason that it seems to cause the colored sputum to clarify more quickly, the supposition being that this drug renders the blood more coagulable. The hypothesis is apparently borne out and substantiated to some extent in practice.

If cough is very severe, codein by mouth in small doses will do much toward quieting the patient. I prefer to use this drug rather than heroin or morphin.

For nourishment the patient should receive 4 ounces of cold milk to which may be added a scant teaspoonful of lime-water every three hours. If the hemorrhage has occurred in the daytime, in the night I like to give the patient liquid nourishment, neither hot nor very warm, but with the chill taken off to relieve the empty stomach and to provide sustenance. If the sputum becomes clear within eighteen hours, semisolid nourishment in the form of dropped eggs may be given. I think it best not to starve the patient more than is necessary, for it seems better to provide means of nutriment which fulfils two purposes. Not only does it give the patient the means of making up the blood loss which has been sustained, but it also quiets and soothes the stomach, causes greater equilibrium of the circulation, more blood being centered in the splanchnic region and less about the affected pulmonary focus.

It is perhaps unnecessary to advise that visitors should not be permitted and that all causes of worry and excitement should be forbidden. The condition of a hemorrhage in a patient in this institution was aggravated and recurrence of hemorrhage stimulated by a domestic factional dispute carried to his bedside and waged there relentlessly at every opportunity which could be obtained until all his visitors were barred, whereupon the patient began to recover.

Formerly our hemorrhage patient, to whom morphin and atropin was administered in full doses, suffered a run of high temperature for a number of days following the hemoptysis. Sharply contrasted with this happening is the normal temperature and pulse of the patient treated by the latter plan. With the gastro-intestinal tract clogged and of little use in carrying off the accumulated toxic material in the bowels it is not surprising that the former condition of high fever, a manifestation of increased toxemia, should obtain. But with a clear and actively functioning bowel the amount and effect of toxemia is reduced to a minimum. Furthermore, the patient is ready to assimilate nourishment as soon as feeding can be safely resumed. Thus double advantage is gained, for, instead of increased wasting, there is quick resumption of an almost normal assimilation, and the relapse occasioned by the period of hemoptysis is of much smaller proportion. The loss of weight, in this latter case, may amount only to a few pounds, whereas formerly a loss of 10 or 12 pounds would occur and the loss sometimes be sufficient to handicap the patient beyond all hope of recovery.

The bedpan may be discontinued on the third or fourth day after the attack, but the patient is not to be allowed up any length of time for at least seven days after the clearing of all color from the sputum. While the patient remains in bed active massage of the lower extremities and body should be prescribed in the form of rubs with liniments, preferably oily camphor preparations, in order to make the patient comfortable and to assist maintaining an equilibrium of the circulation.

I have used preparations of suprarenal extract a sufficient number of times to disclose any material value it might have therapeutically in treating hemoptysis, but nothing has appeared to influence us in its favor. Instead of depending on the physiologic action of the various drugs recommended in treating hemoptysis we prefer the far more certain mechanical effect of depletive purgation.

Only two hemorrhage patients were treated by the production of artificial pneumothorax, and in both instances success was attained. The uncertainty as to which section of the lungs is producing the blood, unless the hemoptysis is strictly unilateral, warns against this practice for obvious reasons.

Constricting the lower limbs with a tourniquet, one at a time, and thus restricting the confines of the circulation, was formerly attempted when the amount of bleeding became dangerously large, but was without extraordinary result.

With the exception of occasional allusions to textbooks I have purposely refrained from citing the literature, in which there is a considerable accumulation of matter on this subject. I have not chosen to compose a critical discourse, but only to state the method of treatment of hemoptysis evolved by observation and practice in a clinic of fifteen hundred patients at the North Reading State Sanatorium.

# SHIP-BORNE CHOLERA

## THE SEA AS A FACTOR IN THE TRANSMISSION OF ASIATIC CHOLERA

CHARLES V. CRASTER, M.D., D.P.H.
ROSEBANK, N. Y.

The seasonal advance of Asiatic cholera from East to West, over mountains and continents, has long been known to follow the paths of human travel and commerce. In the past century many wide-spread epidemics of the disease have embraced the entire continent, but since 1873 it has never prevailed to any extent in this country, although ship-borne cases have occurred from time to time at the various quarantine stations. It may be interesting to record a recent passing of the quarantine line by the disease, in a port separated by a sailing distance of 4,000 miles of ocean from the infected point of departure, and after a direct voyage averaging between ten and sixteen days at sea. The port of New York occupies this position with regard to the Mediterranean and eastern European ports, into which the stream of emigration is easily the largest of any port in the United States and also in the world. The volume of this traffic may be judged by the number of emigrants medically examined at quarantine,[1] which for the year ending 1911 was 533,485 and for 1912, 676,660. The nationality of the greater part of this large army is Italian, Greek, Turkish, Polish, Hungarian and Russian, with a certain number of persons from Asia Minor and the far eastern European lands. The existence of cholera in Italy, Russia and Turkey in Asia, had been noted with the onset of the summer season of 1911. Two deaths from cholera had been reported from Reggio di Calabria, Italy, on June 8, and in June 14 two more cases had occurred at Serrastretta and one at Lungro. The number of cases subsequently reported, however, did not indicate the presence of any extensive epidemic in Europe to warrant the taking of any special preventive measures by the health authorities on this side. The possibility of a cholera invasion of New York City appeared to be remote. The careful routine examination of passengers at foreign ports of departure, with an observation period of five days before sailing, and subsequently the disinfection of baggage and destruction of all foodstuffs carried by emigrants, was considered with reason to be a reliable control on ship-borne cases of the disease, which, with the long period for observation at sea, would seem to constitute a natural barrier against infection. In the following months of June, July and August, a continuous succession of cholera-infested ships arrived at quarantine, New York, and among the detained passengers many cholera carriers were found. It was thus shown that even with the strictest precaution against infection at ports of departure, the distance from an infected locality is no safe-guard against sea-borne cases of cholera. The potential infective ability of the healthy bacillus-carrier also has to be seriously regarded by quarantine authorities. On June 13, 1911, the S. S. *Berlin* arrived in New York and reported the death, with cholera symptoms, of a steerage passenger thirty hours after leaving Naples. Discharges from this passenger preserved until arrival were bacteriologically diagnosed as cholera. The following day, June 14, the S. S. *Europa* from Naples reported one steerage passenger sick with cholera symptoms. On his removal to the Quarantine Isolation Hospital, the disease from which he was suffering was confirmed bacteriologically as cholera. The discharges preserved from another passenger who was ill during the voyage were also confirmed as cholera.

On June 20 the S. S. *Duca degli Abruzzi* from Genoa and Naples reported three cases of cholera-like sickness among the passengers and crew; one of these patients died on arrival at quarantine and one member of the crew died while being conveyed to the quarantine hospital. These two cases were both diagnosed bacteriologically as cholera. A few days later two further cases of cholera developed among the detained passengers from this ship. After five days' detention for observation at quarantine, and one day in Ellis Island, the passengers were released. Four days later, June 30, one of these, an Italian boy aged 17, after proceeding to Auburn, N. Y., was taken sick with cholera-like symptoms, and died on July 1. Cholera was not diagnosed bacteriologically. Another passenger from the same ship, an Italian woman aged 33, sickened in Brooklyn, N. Y., on June 30 with suspicious cholera. She was returned to the quarantine hospital where she died on July 4. Cholera was diagnosed bacteriologically. These two cases were remarkable for the length of time between the known exposure to infection and the development of the disease, it being longer than the usually acknowledged incubation period for cholera. The probable explanation of this occurrence was perhaps an infection immediately before release from quarantine, by an undetected cholera carrier among the detained passengers from the infected ship.

On June 21 a passenger who had suffered from suspicious cholera symptoms was reported on the S. S. *Laura*, which sailed from Patras, Greece, on June 5, calling at the cholera-infected port of Palermo on June 7, where passengers were embarked. No cholera had been reported from Greece at that time and the voyage occupied sixteen days from Palermo. It was not remarkable that two cholera carriers were isolated at quarantine from the passengers who had been in intimate contact with the case on board ship. The immediate result of the development of cholera cases among released emigrants on shore was the issue by the Treasury Department Circular 45, 1911, requiring that the observation period of passengers detained from infected ships be extended to ten days at quarantine, unless after five days' observation bacteriologic examination should show them free from the cholera vibrio. Each case on confirmatory bacteriologic diagnosis was transferred to the Swinburne Island Quarantine Hospital for treatment.

---

[1] Annual Report of the Health Officer of the Port of New

At this time two further cases of cholera had been reported on shore. One, a Spanish sailor, who had arrived in New York on July 2 on the S. S. *Teodoro de Larrinaga,* and after being ashore for fifteen days was suddenly taken ill on the street with severe intestinal symptoms and collapse. Cholera was diagnosed at the Bellevue Hospital, to which he was conveyed, and from which he was removed to Swinburne Quarantine Hospital, cholera being bacteriologically confirmed. This case is remarkable in that there was no cholera reported by the ship on which he traveled, which had come from South America by a round-about route, including a call at Boston before coming to New York. The voyage occupied forty days, and no cholera had been reported from South America. If the infection had taken place on board ship, the incubation period was fifteen days before clinical symptoms became urgent enough to demand hospital treatment. Even if he were a cholera carrier developing an acute attack the initial infection remains a mystery. On July 5 the S. S. *Moltke* arrived from Italian ports with one case of cholera among the crew. The passengers were transferred to Hoffman Island for observation, where eleven further cases developed, making twelve cases of cholera from this ship, and nineteen cholera carriers were found among the detained passengers and crew.

A watchman who had been employed by the quarantine department to guard detained passengers on Hoffman Island, while visiting relatives on July 13, was suddenly seized with intestinal colic. He was transferred to Swinburne Island, where he died two days later; the bacteriologic diagnosis was cholera. This man had been in intimate contact with healthy passengers only, who had been exposed to cholera infection, and the presumption is that he was infected by a cholera carrier.

The S. S. *Perugia,* on arrival on July 15, reported two cases of illness on board at sea, among the passengers and crew. The cases now convalescent were bacteriologically confirmed as cholera.

With the arrival of the S. S. *Venezia* on August 11 from Naples and Palermo a suspected cholera case was reported among the crew. The patient had sickened on August 3, but was well on arrival. Bacteriologic diagnosis was negative for cholera. A passenger had also become sick at sea on August 7 and had died on the following day with cholera-like symptoms. On arrival, specimens from this case were positive for cholera. One cholera carrier was found among the detained passengers. The S. S. *König Albert* reported, on arrival, two sailors sick with cholera symptoms during the voyage from Naples and Palermo. On arrival one of these cases was confirmed bacteriologically as cholera. Two cholera carriers were found among the crew; after routine examination the remainder of the passengers were negative for bacillus carriers.

Three deaths, in children who had clinical symptoms of cholera, during the voyage from Italian ports were reported on August 18, by the S. S. *Re d' Italia.* The discharge preserved from these children, after bacteriologic examination, showed one of these deaths as being due to cholera. One member of the crew and a passenger were sick on arrival in New York, the former case being confirmed as cholera, and one cholera carrier was detected among the passengers in detention. With the arrival of the S. S. *Europa* on August 25, reporting a death from supposed cholera at sea, which was confirmed bacteriologically, the last of the cholera-infected ships were reported at quarantine.

### SUMMARY OF CHOLERA CASES AT NEW YORK, JUNE 14 TO AUGUST 18, 1911

| | |
|---|---|
| Fatal cases of cholera occurring at sea | 6 |
| Cases of cholera occurring at sea, patient arriving well | 4 |
| Cases of cholera occurring at sea, patient arriving sick | 6 |
| Cases developing at quarantine after arrival | 15 |
| Cases occurring among released ship's passengers and crew | 3 |
| Cases among quarantine employees | 1 |
| Cholera-bacillus carriers detected at quarantine | 31 |

### SPECIAL MEASURES TAKEN BY THE HEALTH AUTHORITIES

In consequence of the continual arrival of cholera-infected ships in the port of New York, special measures were instituted by the federal and state health authorities, including the issue on July 16, by the U. S. Treasury Department, of Circular 47, requiring the detention of all steerage passengers from cholera-infected ports until bacteriologic examination had proved them not to be cholera carriers. To insure the proper carrying out of the routine examination necessitated by this order the quarantine laboratory staff was reenforced by trained assistants from the state laboratory at Albany and from the U. S. Public Health Service at Washington. The steamship owners were urged that they advise their agents abroad not to accept immigrants from infected localities, in order to prevent congestion at New York quarantine. State and local authorities were asked to exercise special superveillance over newly-arrived emigrant laborers, and in the event of the occurrence of a case of acute gastro-enteritis or diarrhea to notify the State Board of Health without delay. Expert aid was offered by the federal authorities to any local health board requiring aid for the diagnosis of suspicious illness or for the inauguration of special preventive measures.

### THE ROUTINE EXAMINATION FOR CHOLERA CARRIERS

The compulsory bacteriologic examination of all passengers from cholera-infected ports made necessary by the treasury order of July 16, 1911, required the taking of rectal swabs from every steerage passenger, as well as from the members of the crew. With practice the routine procedure became most expeditious, so that a thousand or more emigrants could easily be handled in one day. In the beginning, swabs from the rectum were deposited in sterile tubes, which were conveyed to the laboratory and there inoculated into Dunham's peptone solution. To save time and facilitate the procedure enough tubes of Dunham's medium were conveyed on board the steamship in wire baskets, holding one hundred each. The swabs, similar to those used for diphtheria work, were sterilized in paper bundles of fifty or one hundred. The passengers were first separated, the women and children being handled by a staff of women doctors and nurses. Each passenger with his name card was rapidly passed before the doctors in a convenient room such as the dispensary or ship's hospital. The swab was moistened in peptone water and inserted well above the anal sphincter. It was found best to obtain a well fecal-stained specimen, which was dropped into a peptone tube and numbered to correspond with the number on the identification card.

On completion of the procedure the peptone cultures were conveyed ashore and incubated for six hours at 37 C. (98.6 F.). Subcultures were then made in fresh peptone water and incubated for from nine to ten hours. Smears from the subcultures were stained with dilute carbolfuchsin (1:7) and examined microscopically. Any vibrio found was examined for motility and plates of alkaline agar made (3/10 to 5/10 alkaline to phenolphthalein). After incubation for from twelve to twenty-four hours the plates were examined, and any suspicious organisms present were tested for agglutination against an anticholera serum of high titer. For the purpose of simplifying the procedure of vibrio detection an attempt was made to utilize the known fermentative action of vibrios on saccharose for diagnostic purposes. An alkaline saccharose-peptone water was employed containing phenolphthalein as an indicator, the presence of sugar-fermenting vibrios being shown by the decolorizing of the medium. By the procedure good results were obtained in the limited time the special medium was used.[2]

A passenger found harboring the cholera vibrio was immediately isolated to Swinburne Island Hospital, where he was treated as a cholera patient. On a negative bacteriologic finding all passengers were discharged from detention. During the four months of routine examination for cholera carriers, 26,678 passengers were bacteriologically examined at quarantine, the number for each month being: July, 1,777; August, 5,105; September, 5,700; October, 9,389; November, 5,807.

### THE CHOLERA VIBRIO

The peptone water for enrichment, and similarly the Liebig beef-agar medium for plates were employed, with an alkaline reaction to phenolphthalein of from 0.3 to 0.5 per cent., and this was found to be the most favorable reaction for the growth of the cholera vibrio. The cholera red was not obtained to any degree in peptone cultures containing a mixed intestinal flora, it was, however, fairly consistently present in pure cultures.

The colonies of the cholera vibrio in pure culture on alkaline agar plates, although readily distinguishable from those of other intestinal bacteria, were not so easily differentiated from the cholera-like vibrios. After twenty-four hours' incubation the growth was seen flattened, round colonies, with a clear-cut even edge, finely granular, with sometimes larger granules at the centers; yellow by reflected and bluish by transmitted light. There was also an opalescent appearance by transmitted sunlight. The odor was generally fecal, and the colonies presented an appearance of extreme fluidity, so that when touched with a platinum needle they tended to flow.

Typical motility was generally present in twelve-hour peptone-water cultures. In making a hanging-drop preparation, it was found that if any pellicle present were gently moved aside by tilting the tube and the platinum loop inserted just below the surface actively motile organisms were more certain to be obtained. The characteristic motility could be strikingly observed with the dark-field illuminator.

### THE CHOLERA-LIKE VIBRIOS

A striking feature observed during the routine examination for carriers was the large number—over one hundred—of vibrios isolated from the fecal cultures, which gave a negative reaction with the specific serum. A detailed description of these atypical vibrio forms I have made elsewhere.[3] The morphologic and cultural resemblances to the cholera vibrio were so close in some instances that definitely distinctive features were difficult to find. As a rule the indol reaction was absent or slight, and they were all non-pathogenic to animals, even in large doses. In some of the strains isolated, saprophytic properties, such as pigment formation, clearly indicated the nature of the organism.

The presence of these aberrant vibrio types in association in the cholera cases has been frequently observed, notably by Zlatogoroff,[4] and by McLaughlin and Whitmore[5] in the Philippines, but the exact significance of the occurrence is yet undetermined. A curious incident bearing on this association was noted at quarantine in the isolation of the greatest number of non-cholera vibrios at one time, in the passengers of a vessel among whom two cholera carriers were found.

### THE DIAGNOSIS OF CHOLERA

The occurrence during cholera epidemics of non-pathogenic vibrios, typically cholera-like in morphology, motility and cultural appearances, has caused such characters to appear of less account in the final differentiation of the cholera vibrio. Of more importance in the diagnosis of cholera are certain reactions of the body resulting from the invasion by the cholera vibrio, which are manifested especially in a powerful activation of those tissues concerned in the formation of the various cellular antibodies, the bacteriolysins, the agglutinins and precipitins. This phenomenon is witnessed in cholera convalescents, as well as in animals immunized against the specific organism.

*Agglutination.*—Although the agglutinating power of various strains of the cholera vibrio varies somewhat at times, it is always sensitive to the action of a strong antiserum, positive agglutination taking place with high dilutions of the serum, such as 1:10,000 and 1:32,000. The observation of agglutination may be carried out by the macroscopic method, using Wright's tubes. An emulsion of a 24-hour-old agar culture of the suspected organisms in broth or normal saline is mixed with the antiserum in various dilutions and drawn up into glass sedimentation tubes, which are sealed in the flame. Readings are taken at the end of two hours at 37 C. (98.6 F.), or twenty-four hours at room temperature. Controls with normal saline or normal horse-serum should be employed at the same time. Similarly, agglutination may be observed in hanging-drop preparations with the microscope. For general purposes the reaction is satisfactorily and quickly carried out by means of a macroscopic method with the naked eye. On an ordinary glass slide, an emulsion of the suspected organism is mixed with the diluted antiserum by means of a platinum loop. Immediate agglutination takes place with the cholera vibrio as shown in the formation of floccules and clumps in the hitherto opaque emulsion. It was observed that the maximum agglutination power of the cholera vibrio was seldom found to be as high as the titer of the serum employed. In suspected cholera convalescents, in which the cholera vibrio cannot be demonstrated in the stools, the patient's blood-serum may be tested for agglutination against a known cholera culture.

*Pfeiffer's Reaction.*—The reaction of Pfeiffer depends on the effect of a powerful cholera bactericidal serum on the cholera vibrio. An emulsion of the suspected organism is injected into the peritoneal cavity of a guinea-pig, together with the bactericidal serum. A positive reaction is given if specimens of the peritoneal fluid removed at intervals of a few minutes show disintegration of the vibrios. A control experiment should be made with normal serum. This reaction is specific for cholera and enables a definite diagnosis of cholera to be made.

[5] McLaughlin and Whitmore: Philippine Jour. Sc., 1910, v, 403.

*Complement-Fixation.*—It has been shown by the reaction of Bordet and Gengou[6] that specific serums contain a certain substance (*substance sensibilisatrice*) which, when combined with its corresponding bacterial antigen, has the power of fixing another substance "complement," present in all normal serums, in this way preventing hemolysis when added to sensitized capsules. This binding of complement by a specific cholera serum and a culture of cholera vibrios may be employed for the differential diagnosis of an organism suspected to be the cholera vibrio. The anticholera serum is inactivated by heating at 55 C. (121 F.) for thirty minutes. A twenty-four-hour agar culture of the suspected organism is used as antigen, previously killed by heating to 60 C. (140 F.) for one hour and dissolved in physiologic salt solution. If the inactivated specific serum and the bacterial culture (antigen) is combined with normal guinea-pig serum to supply complement and after incubation for an hour at 37 C. is then added to a mixture of hemolytic serum and blood-corpuscles, no hemolysis takes place if the suspected organism is the cholera vibrio, complement having been absorbed by the combination of the specific serum with its antigen, the cholera vibrio.

### THE CHOLERA CARRIER

It is well known that perfectly healthy persons may harbor the causative agents of certain diseases, notably in the case of typhoid fever and diphtheria, either as a persistent continuance of the organism in the secretion of the body after an attack of the disease or as an infection with the specific microbe without manifest subjective symptoms. The existence of a parallel condition in persons during cholera epidemics was observed by Rumpel in Hamburg, Metchnikoff in Paris, Vogler in Altona and Ivanoff in Berlin.

Thirty-one cholera-bacillus carriers were found among ships' passengers bacteriologically examined at quarantine during the period from July to November, 1911. A definite history of a recent intestinal attack was obtained in four of these carriers. The proportion of carriers detected to examinations made was considerably less than the number reported under similar conditions at Naples, 1910; at that time twelve carriers were found in 1,400 persons.[7]

*Treatment.*—Every person who was a cholera carrier was isolated and treated as a cholera patient. The difficulties in the treatment of such carriers are inseparable from the apparent condition of good health and freedom from subjective symptoms which are always present in these patients. Strict isolation was enforced, with all fecal matter rigidly sterilized until a negative bacteriologic finding was obtained. It was observed that a carrier detained at quarantine discharged cholera vibrios in the stools at irregular periods, between which intervals a negative finding might be obtained bacteriologically.[8] These negative periods were frequently of several days' duration. The potential danger to the public in the careless release from detention of a carrier of this kind would be manifestly great.

*Duration of the Infective Period.*—The length of time during which a cholera-bacillus carrier continues to be infective has been stated to vary within wide limits. Zlatogoroff[9] has recorded the isolation of the cholera vibrio from the stools of a person one year after recovery. Pasquale[10] succeeded in isolating the specific organism from the stools twenty-seven days after an attack of cholera. Saccone,[7] with an extensive experience, found cholera carriers to be infective between eleven and fourteen days. The majority of the carriers isolated at quarantine remained infective from a few days to two weeks or more; in one case the comma bacillus was present for fifty-four days.[8] Three or more negative bacteriologic findings at intervals of two days for a week or longer were required before a cholera carrier was released from detention.

### THE CHOLERA CASES

Twenty-four cases of cholera were treated at the Quarantine Isolation Hospital, with thirteen deaths; a rate of mortality of 54.1 per cent. Five of these patients were moribund on admission. The duration of an attack of cholera and the rapidity of its termination is dependent on the virulence of the infective process, so that the characters of the disease varied somewhat in the individual. In the acute cases the classic signs of vomiting, purging, collapse, muscular cramps and coma were early in evidence, the stools being sometimes continuous, with incontinence of feces. The typical rice-water evacuations seldom showed any fecal staining and from them the comma-bacillus was obtained in pure culture. One case of cholera sicca was remarked; the patient had no stools; the symptoms were collapse with cyanosis, with an abdomen distended with fluid contents. Recovery took place. The milder cases of cholera showed only a slight diarrhea with no great accompanying physical discomfort.

Although the skin temperature is subnormal in cholera, the rectal temperature was found to be consistently high (102 to 103 F.), with subnormal intervals throughout the attack. This fluctuating rectal temperature at times showed wide ranges during the day; a difference of 6 degrees Fahrenheit between the morning and the evening readings was recorded, and a subnormal morning temperature frequently rising to 102 to 103 in the evening. This oscillating temperature often persisted for some days after all clinical symptoms had disappeared. In certain of the fatal cases in which excessive reactive processes were manifested in the hyperpyrexia the rectal temperature before death rose to 109 F.

Four patients succumbed on the first day of illness, one of these between sunrise and 11:45 a. m. and another within eleven hours of onset. Three died on the third, three on the fourth and one each on the second, sixth and eighth days, respectively. In the non-fatal cases the cholera vibrio persisted in the stools for various periods of time after the cessation of acute symptoms, usually from the seventh to the fourteenth day, and exceptionally for much longer periods.

### SUMMARY

During June, July and August, 1911, ten cholera-infected ships arrived at quarantine, New York, from Mediterranean ports, bringing a total of 5,411 passengers and 1,789 members of ships' crews having been exposed to cholera. Six patients arrived sick and four were convalescent from the disease. Twenty-four cases were

[10] Pasquale: Glor. med. d. R. esercito ed R. marina, 1893, p. 936,

treated at the isolation hospital on Swinburne Island, with thirteen deaths. Two cases occurred among released passengers in New York City and state, and one member of a ship's crew. One fatal case occurred among the quarantine employees. Thirty-one cholera carriers were detected by routine examinations; these were isolated and treated as cholera patients. Four of these gave definite histories of a recent sickness with diarrhea. During the four months of routine examination of passengers from infected ports for cholera carriers, 26,678 persons were bacteriologically examined.

Over one hundred non-cholera vibrios were isolated during the routine examination. Many of these resembled the vibrio of cholera so closely that no difference was possible, except the negative reaction with the specific serum. In the cholera cases, a fluctuating rectal temperature of a degree above or below normal persisted for some days after all clinical symptoms had subsided, and after the specific organism had ceased to be demonstrated in the stools. The cholera carriers with no subjective symptoms could be infective up to fifty-four days. The cholera cases remained infective by the presence of the comma-bacillus in the stools for one to two weeks after all symptoms had abated, exceptionally for longer periods.

### CONCLUSIONS

Time and length of voyage from infected districts does not confer any special immunity against the occurrence of Asiatic cholera in this country. The well-established existence of the cholera-bacillus carrier has altered considerably the aspect of cholera prevention, for we have to deal not only with real, but also with potential agents of infection. The high efficiency of present-day quarantine procedures has rendered the possibility of spreading infection from cholera cases extremely slight. The real danger to the public is not alone the person sick with the disease, but also the person infected with the specific organism and presenting no apparent symptoms of illness. In typhoid carriers the gall-bladder is known to be the store-house of the infecting organism. That a similar condition may exist with cholera carriers is suggested by the observations of Greig,[11] who demonstrated by cultural methods the presence of the cholera vibrio in the gall-bladder eighty-one times out of 271 cases of fatal cholera. In the prevention of cholera, besides the effective isolation of the sick there has developed in our experience at quarantine, the necessity of extreme caution in the release of contacts or fellow passengers from detention, before a routine bacteriologic examination has proved them free from the cholera vibrio and even after such a routine procedure there remains always a possibility of the escape of a bacillus-carrier who may have been examined during a negative interval of an intermittent discharge of the infecting organism.

When sporadic cases of cholera occur in any community (the so-called cholera nests) it would seem that the bacteriologic examination of drinking-water and of food, although advisable always, is not of the same importance as a diligent search for the true source of infection, the infected, presumably healthy person, the proper means for whose detection, although involving a state in great outlays of money and time, are of necessity justified in emergencies for the proper preservation of the public health and confidence.

I am indebted to the courtesy of Dr. F. C. Clark, chief medical officer of Swinburne Island Isolation Hospital, Quarantine, N. Y., for the opportunity to review the clinical reports of cholera cases and cholera carriers.

# THE "WASSERMANN-FAST TABES"

## A SEROLOGIC PRECURSOR OF TABOPARESIS

D. M. KAPLAN, M.D.
Director of Laboratories, Neurological Institute
NEW YORK

The question of tabes from a diagnostic standpoint offers very few difficulties. Where clinical manifestations are few and indefinite, laboratory aids as elaborated by the latest serologic methods give ready and at times conclusive evidence of the presence of this disease. It is not my purpose to travel over well-beaten paths of diagnosis, be it clinical or serologic, but to offer to the neurologist a guide to therapy and to assist in the rendition of a prognostic opinion in this disease. To the serologist it may also be of interest to know that some forms of tabes behave differently from a serologic attitude than others. As there are different types of tabes clinically, so there are also various serologic manifestations of this disease. The clinician is thoroughly familiar with the form of disease which will ultimately present the full picture of taboparesis and is also acquainted with the type that is purely degenerative and lacks all evidence of activity in the meninges. The serologic development of the last few years in connection with diseases of the nervous system not only gave us the laboratory accompaniment of this disease, but also enabled the careful observer to point out here and there occurrences in the analysis of the serum and the fluid that are as important as the ability to diagnosticate this malady. It seems to me that neurologists are beginning to recognize the value of analyses of the cerebrospinal fluid and are gradually becoming more familiar with the utilization of laboratory data. One of the facts that I, together with Dr. L. Casamajor, pointed out in 1912, in connection with tabes, was the very favorable clinical and serologic reactions obtained with tabes of the "hyperlymphocytic" type. Our observations still hold good after a large additional number of such cases has been studied. On the other hand, we were considering the treatment of tabes that showed no cerebrospinal fluid abnormalities as rather inconsistent. Taking these things together, one can at a glance appreciate how much less informed we were in regard to the gauging of treatment before the era of "neurologic serology" as compared with the newer methods of procedure. The value of serologic data increases with their number, and it is with this in view that I have undertaken the writing of this article.

Having studied serologically over 650 cases of tabes of various types, and in some instances having observed the changes in the serum and cerebrospinal fluid on as many as twelve occasions in the same patient to note the adequacy of therapy, I had the opportunity to note the effect of various therapeutic procedures on the serology of a large proportion of cases and carried away the impression that there are distinct types of tabes that can be properly judged only after a thorough course of strenuous treatment. Although the patient may at the time of the first analysis show the serologic picture of tabes of the "hyperlymphocytic" type, the result of vigorous treatment will tend to show whether or not the serology is amenable to therapeutic effort. I have observed a number of cases in which despite the frequency, dosage and specificity of the remedy, the serum would still show a positive Wassermann reaction. A few more advanced cases would also show an unchanged positive Wassermann in the cerebrospinal fluid. I have designated these cases as "Wassermann-fast tabes" in contradistinction to those forms of the disease that, as shown by the Wassermann test, yield readily to therapeutic efforts. When one studies the serology of general paresis one is struck with the large percentage of positive Wassermann reactions obtained on the serum and spinal fluid of this disease. When the subject of percentage of positive results is studied critically, particularly the observations that give 100 per cent. positive reactions even in general paresis, one is fully justified in asking the question: Is it possible that the cases reported were never treated with the remedies commonly used in such cases? Still further: If they were treated, some even with great thoroughness, is it possible that the Wassermann reaction remained unchanged and gave 100 per cent. of positive results? These questions are rarely asked and the results are accepted unchallenged. There should be no 100 per cent. of positive Wassermann reactions, and the experience of the majority bears out my contention. The reason why the percentage of positive Wassermann reactions in the serum from tabetics ranges between 55 and 70 is that the treatment of many of these cases was, from the point of view of serology, apparently successful. The low percentage of positive results also speak for the amenability of the serology of this disease to therapy, for it is self-evident that the easier it is to influence a disease with proper therapeutic measures, the fewer positive results are obtained with the Wassermann test. The number of cases of tabes that give positive Wassermann reactions are composed chiefly of patients who were not treated recently, or were treated insufficiently or belong to the type of cases of "Wassermann-fast tabes." The reason why general paresis gives the greatest percentage of positive Wassermann reactions is due chiefly to the fact that very few positive reactions in this disease become negative after treatment, in other words, general paresis typifies the Wassermann fast neurologic disorder of syphilitic origin.

TABLE 2.—RESULT OF TEST IN TABOPARESIS, CASE 2*

| Treatment | Serology Performed | Serum W. R. | Cerebrospinal Fluid Analysis | | |
|---|---|---|---|---|---|
| | | | W. R. | Glob. | Lymphoc. |
| Hg. inunct. 30 doses 4 gm. | 3 weeks after therapy. | + | + | + | 53 |
| 6 weeks later, 21 injections Hg. salicyl. | 4 weeks after therapy. | + | + | — | 53 |
| 8 months later, 606 0.6 in vein | 4 weeks after | + | + | — | 50 |
| 1 week later, 606 0.6 in vein | 3 weeks after | + | + | — | 41 |

* Reduction of Fehling's solution normal throughout.

The negative reactions obtained with general paresis are composed chiefly of those of the early cases which frequently give a negative Wassermann reaction in the serum and a positive result in the cerebrospinal fluid. It is very proper to apply to the serologic analogy of the "Wassermann-fast tabes" and its relation to general paresis the dictum of Charles Darwin: *Natura non fecit Saltus*, which is borne out by the clinical course of this type of locomotor ataxia. In the twelve cases of the "Wassermann-fast" type observed by me, nine patients developed full-fledged taboparesis and three died shortly after the paretic signs manifested themselves. To cite a few cases:

Case 1.—Mr. H. S., aged 44, married; no children; lues eighteen years ago; shooting pains; girdle crises; Argyll Robertson pupils; Romberg phenomenon; no mental symptoms. Serology before treatment, positive Wassermann reaction in serum and fluid; excess of globulin; 60 lymphocytes per cubic millimeter; prompt reduction of Fehling's solution.

Case 2.—Mr. Sp., aged 52, married; wife had four miscarriages. Lues at 20; markedly ataxic; girdle crises; Argyll Robertson pupils. Serology before treatment, positive Wassermann reaction in serum, same in fluid; slight excess of globulin; 36 lymphocytes per cubic millimeter; normal reduction of Fehling's solution.

TABLE 2.—RESULT OF TEST IN TABOPARESIS, CASE 2*

| Treatment | Serology Performed | Serum W. R. | Cerebrospinal Fluid Analysis | | |
|---|---|---|---|---|---|
| | | | W. R. | Glob. | Lymphoc. |
| 0.6 salvarsan intraven. | 2 weeks after therapy | + | + | + | 33 |
| 1 week later the same | 3 days after therapy | + | + | + | 26 |
| 10 days later 914 | One week after therapy | + | — | — | 21 |
| 1 day later 914 | 3 days after therapy | + | — | — | 21 |
| 1 week after 914 intraven. | One week after therapy | + | — | — | 16 |

* Reduction of Fehling's solution normal throughout.

## REPORT OF CASES

The treatment given these patients by no means represents the most active specific therapy that could be employed. The reason for this was the discouragingly rapid decline in the general health of the patients. The first one of the two died two months after the last treatment. The second patient developed taboparesis one year after the last treatment and died in a paretic decline.

These cases of tabes represent the absolute "Wassermann-fast" variety of the disease. It is sometimes, however, possible to obtain a weakly positive result after very vigorous treatment, and on very rare occasions even a complete negative Wassermann. The latter, however, does not remain negative for a long time but may return to positive a week or two after the last negative analysis. These are only relatively fast tabetics whose Wassermann reaction sooner or later will reassume its absolute fast nature, initiating in the course of time the clinical signs of taboparesis. Time will tell whether salvarsan or any other as yet undiscovered remedy used in large and frequently repeated doses will ever tend to ward off the approach of an impending taboparesis in a tabetic; at present it seems that frequently repeated small doses of neosalvarsan produce very encouraging changes in the psychic manifestations of the disease. In my opinion a patient with tabes who presents an absolute or even a relative "Wassermann-fast" tendency should be given the benefit of this treatment with small doses (0.3 gm. of neosalvarsan) every third or fourth day. I do not think that the Wassermann will be influenced at all, or at most an absolute fast condition could be made a relatively fast one. In fully developed general paresis one encounters the absolute "Wassermann-fast" condition more often than in any other syphilitic disease of the nervous system, and as the serology of a tabetic inclines toward assuming the "Wassermann-fast" tendency, it is my opinion that the clinician should be on the lookout for clinical evidences of an approaching taboparesis.

# AN EXPERIMENTAL AND CLINICAL STUDY OF INTERNAL HYDROCEPHALUS *

WALTER E. DANDY, M.D.
AND
KENNETH D. BLACKFAN, M.D.
BALTIMORE

Numerous methods have been suggested for the treatment of internal hydrocephalus, none of which have been productive of satisfactory results. So long as the etiology of this condition remains obscure, the treatment must necessarily be only symptomatic. In the hope of clarifying its etiology and thus affording a rational working basis for its relief, we have undertaken this investigation.

The present communication, which is presented as a preliminary report, includes observations on dogs after the production of experimental hydrocephalus, together with observations on patients suffering from the disease. We have also considered the manner and the place of formation and of absorption of the normal cerebrospinal fluid and the relation of these factors in the production of this pathologic condition.

## HYDROCEPHALUS EXPERIMENTALLY PRODUCED

From a survey of the literature we have been unable to find any record of hydrocephalus having been produced experimentally. In our experiments an obstruction has been placed in the aqueduct of Sylvius, and thus the only way of exit for the cerebrospinal fluid from the third and the lateral ventricles has been occluded. An internal hydrocephalus has invariably resulted. The following is the procedure:

A bilateral suboccipital decompression is made through an occipital midline incision. After exposure of the cerebellum it is retracted upward, and the foramen of Magendie carefully enlarged by incising the membrane joining the cerebellum and medulla. A piece of cotton in a small gelatin capsule, placed on the end of a graduated carrier, is inserted through this enlarged foramen of Magendie and gently passed along the floor of the fourth ventricle into the aqueduct of Sylvius, where it is deposited by withdrawal of the carrier. The symptoms which are observed following the operation are principally lethargy and vomiting (general pressure symptoms) dating from the time of operation. When carefully performed there are no irritative or destructive symptoms from the operation. This hydrocephalus therefore is due to a purely mechanical obstruction in the aqueduct, as there is no interference with the veins of Galen.

Since the venous obstruction is considered a possible cause of hydrocephalus, a series of experiments was conducted in which the vein of Galen and the straight sinus were ligated. In none of these cases did hydrocephalus result.

## ABSORPTION OF THE CEREBROSPINAL FLUID

There are many theories concerning the place and manner of the absorption of cerebrospinal fluid. In the study of absorption in the experimental and clinical work we have used almost exclusively phenolsulphonephthalein. This inert colored solution, first introduced into practical medicine as a renal test by Rowntree and Geraghty, has since been shown to be an accurate index of fluid absorption when the renal function is normal. It is very stable, is excreted in the urine with great rapidity, is easily detected in minute traces and is readily adapted to accurate quantitative estimation.[1]

Since an internal hydrocephalus can be experimentally produced by occluding the aqueduct of Sylvius, it is evident that absorption of fluid from the ventricles is less rapid than its production. In the studies of the absorption from the ventricles of patients with an internal hydrocephalus due to obstruction in the aqueduct, after the introduction of phenolsulphonephthalein in the lateral ventricles, there is excreted in the urine from 0.25 to 1 per cent. during a period of two hours; but when it is injected into the subarachnoid space of the same patient there is an excretion of from 35 to 60 per cent. in the urine in the same period of time. This demonstrates that the absorption of cerebrospinal fluid takes place almost entirely in the subarachnoid space.

It is evident that the fluid must be absorbed either into the blood or lymph-vessels. When phenolsulphonephthalein or other inert colored solutions are injected into the subarachnoid space. they appear in the lymph of the thoracic and right lymphatic ducts only after an interval of from thirty to fifty minutes, and only a faint trace is present even after two hours, whereas, they appear in the blood in three minutes and in the urine in six minutes and, as mentioned above, from 35 to 60 per cent. is excreted in the urine at the end of two hours. These facts indicate that the cerebrospinal fluid passes directly into the blood and that the lymph-vessels are not concerned in its absorption. There are three principal views regarding the manner in which the cerebrospinal fluid passes into the blood: (1) by means of stomata arranged along the venous sinuses; (2) through the pacchionian granulations, and (3) by a general process of osmosis.

When a suspension of fine granules is injected into the subarachnoid space the granules do not pass into the blood except in very minute quantities and after a long interval of time. Consequently the assumption of special openings (stomata) from the subarachnoid space into the venous sinuses seems unlikely. This applies to granules injected into the subarachnoid space under normal conditions of pressure. If pressure is used, especially on young tissues, foreign materials can easily be forced into the veins. In adult animals this requires a very high pressure. It should be noted that stomata were formerly believed to exist in the peritoneum to explain the absorption from this cavity, but this has been shown not to be the case.

That the pacchionian granulations do not play any special rôle in absorption can, we think, also be shown. These granulations are absent in many species of animals, are always variable in number and size and develop principally in adult life. After fine granules are injected into the subarachnoid space, local collections are deposited along the sinuses—especially the superior longitudinal sinus—in the interstices of the fibrous meshwork which forms the walls of the sinuses. These deposits are in all essentials similar to those in the pacchionian granulations. There is always a layer of dura and arachnoid separating these masses of granules from the blood in the veins. This is a much greater mechanical barrier to absorption than is present in the exposed capillaries of the pia-arachnoid.

After the injection of phenolsulphonephthalein into the spinal subarachnoid space (the communication with

---

* From the Departments of Surgery and Pediatrics of the Johns Hopkins University.

[1] It should be emphasized, however, that ordinary solutions of phenolsulphonephthalein are made up in alkali, which is sufficient to militate against its use in the central nervous system. To overcome this defect we use a neutral solution specially prepared for us by Hynson, Westcott & Co.

the cerebral subarachnoid space being closed), there is found to be a quantitative absorption proportionately as great as from the entire subarachnoid space. This shows that the absorption from the spinal subarachnoid space is similar to that from the cerebral. It is obvious, therefore, that cerebrospinal fluid is absorbed by a diffuse process from the entire subarachnoid space and is not restricted to any special locality, as, for instance, the region of the venous sinuses or the pacchionian granulations. From the foregoing observations, absorption from the subarachnoid space appears to be very similar to that from the pleural and peritoneal cavities, though it is somewhat less rapid.

### FORMATION OF THE CEREBROSPINAL FLUID

It has long been known that there is an active formation of cerebrospinal fluid as evidenced by the rapidity with which the fluid reforms after it has been withdrawn either by lumbar or ventricular puncture. The endowment of the chorioid plexus with an elaborate blood-supply indicates that it is a structure with a special function. Since the work of Faivre (1854) and Luschka (1855) showing the secretory character of the cells, the chorioid plexuses have been regarded as glands, from which at least part of the cerebrospinal fluid is formed. The discovery of secretory granules by *intra-vitam* staining by Francini, and also by Bibergeil and Levaditi, leaves but little doubt as to the secretory nature of this function.

We have shown that practically no absorption takes place in the ventricles, at least under the pressure from an abnormal accumulation of fluid. Since this is true and since hydrocephalus results from an experimental block in the aqueduct of Sylvius, it is evident that the fluid forms in the ventricles. These facts demonstrate an irreciprocal permeability of the fluid-forming structures, and emphasizes the secretory rather than the mechanical formation of the cerebrospinal fluid.

### OBSERVATIONS ON PATIENTS WITH HYDROCEPHALUS

In these cases we have applied the phenolsulphonephthalein test in order to determine the amount of absorption from the ventricles, the amount of absorption from the subarachnoid spaces and whether or not there was free communication between the ventricles and the subarachnoid spaces. Subsequently the results of these tests have been compared with the pathologic findings. Phenolsulphonephthalein, as has been said before, is perfectly harmless, and when used for injection into the ventricles or subarachnoid spaces produces no reaction.

From observations made on patients without hydrocephalus it has been possible to establish a normal standard for the excretion of phthalein after its injection into one or the other of these cavities. In all cases the kidney function has been shown to be normal. When injected into the ventricles phenolsulphonephthalein normally appears in the urine in from ten to twelve minutes, and after two hours from 12 to 20 per cent. is excreted. After its injection into the subarachnoid space, it appears in the urine in from six to eight minutes, and from 35 to 60 per cent. is excreted in two hours.

When phenolsulphonephthalein is injected into the ventricles, it appears in the lumbar spinal fluid within two or three minutes. In hydrocephalus this becomes a most important test, for it enables one to determine accurately the patency or obstruction of the channels of exit from the ventricles to the subarachnoid space. Furthermore, fluid passes upward into the ventricles after the injection of phenolsulphonephthalein into the lumbar subarachnoid space.

By comparing the results of these tests with those obtained in hydrocephalus, we are enabled to establish two types of this disease. In the first type, after the injection of phenolsulphonephthalein into the ventricles, the time of its appearance in the urine is greatly delayed (from twenty to forty-five minutes) and the quantity excreted in two hours is practically negligible (from 0.25 to 1 per cent.). The excretion of phenolsulphonephthalein in this group after its injection into the subarachnoid space, however, is practically normal (time of appearance from six to eight minutes, quantity excreted in two hours from 35 to 60 per cent.). Furthermore, after the injection of phenolsulphonephthalein into the ventricles, it has not, in the cases observed, appeared in the spinal fluid. In this group, we have found at necropsy an obstruction to the passage of cerebrospinal fluid from the ventricles to the subarachnoid space. In two cases there was a congenital closure of the aqueduct of Sylvius, a third showed old adhesions obliterating the basal foramina of Magendie and Luschka, and in the fourth these foramina were closed by a thick tuberculous exudate which completely covered the base of the brain.

In the second type the excretion of phenolsulphonephthalein after its injection into the subarachnoid space is greatly diminished (from 8 to 15 per cent.), and the appearance time delayed (from twenty to thirty minutes). The amount excreted after its injection into the ventricles likewise is greatly diminished, undoubtedly due to the low subarachnoid absorption. In contradistinction to the first type the communication between the ventricles and the subarachnoid space is open. This is shown by the prompt (from two to three minutes) appearance in the spinal fluid of phenolsulphonephthalein after its injection into the ventricles. We have had the opportunity of examining two patients of this type, but as yet have made no pathologic observations. In both there has been an antecedent history of meningitis, one of which was due to the meningococcus.

These two types of hydrocephalus may be readily differentiated by determining the patency or occlusion of the channels of exit from the ventricles. In Type 1 these channels are obstructed and hydrocephalus results because there is no absorption from the ventricles. In Type 2 the channels are patent and hydrocephalus is due to the diminished absorption from the subarachnoid space.

It is a pleasure to express our gratitude to Professors Halsted, Howland and Cushing for suggestions during the course of the work, and for the opportunity of carrying out these investigations.

---

# SOME RECENT CONCLUSIONS ON ABDOMINAL ROENTGEN-RAY WORK

ANTHONY BASSLER, M.D.
Professor of Clinical Medicine, New York Polyclinic Medical School and Hospital; Visiting Physician, New York Polyclinic Hospital; Chief Gastro-Enterologist, German Poliklinik; Visiting Gastro-Enterologist, Peoples Hospital
NEW YORK

At present the Roentgen-ray bismuth method of diagnosing conditions of the alimentary canal is generally utilized. Since the work of Holzknecht was advanced, roentgenologists, and following them, surgeons and internists, have been accepting various reports as diagnostic. During the present winter I have checked up my Roentgen-ray findings with those of the laboratory and those noted at operation, and a few of the facts of the Roentgen-ray method of examination alone seem worthy of presentation.

After a trial with several methods, I find that plugging the cardia so as to retain the bismuth in the esophagus and then making stereoscopic plates of the esophagus while the patient is in the standing position is the best means of diagnosing new growth of the esophagus before marked stenosis exists. This is true of studies of the gullet itself and also of extra-esophageal conditions. The second method that answered to good purpose was giving the bismuth salt in about 25 gm. quantities suspended in two ounces of syrup of acacia. This makes about four swallows and thickly coats the interior of the gullet, giving fairly sharp shadows for studying the course of the canal as well as its rugae and for gaining an idea of the structure when viewed fluoroscopically.

In the study of motility and exit from the stomach in 203 cases of distinct gastroptosia, in which hourly x-ray observations were made, the conclusion was plain that the x-ray method of diagnosing stasis in the stomach is not as practical as the test-meal method. One hundred and twenty-six of these cases examined by the bismuth x-ray method showed delay of exit of six hours or more, while only thirty-one showed the delay by the test-meal method. In some instances the bismuth x-ray method showed a delay of nine hours or more, when the test-meal method showed a normal evacuation. Instances were encountered in which bismuth was present in the stomach as late as eighteen hours after ingestion, while the stomach on a mixed meal was empty in four and one-half hours. Further, in many cases, apparently from one-fourth to one-half of the amount of bismuth ingested was present in the stomach six hours afterward, and the studies of the pylorus and of the motility as seen in the plates and the test-meal findings showed the exit as well as the course of bismuth to the ileocecal region to be normal. It is apparent, whatever has been advanced to the contrary, that the method of examination by food extraction is decidedly more to be depended on in gaining an idea of exit from the stomach than is the bismuth x-ray method, for it was strongly suggested that foods pass from the stomach in decidedly less time than will bismuth or any other form of metal salts used to throw a shadow, probably because of the pulverized salts adhering to the mucosa. Studies were made by giving the bismuth suspension after a mixed meal hoping that the meal would cause a normal exit of the bismuth, but it was found in a number of instances that the bismuth caused a delay in the exit of the food; and, if the bismuth was given before the food was taken, the delay of the bismuth was more marked in that it even held the food back somewhat.

Those cases in which a rectal injection of bismuth, to outline the colon, and bismuth by mouth were given at the same time showed, in hourly studies of the stomach afterward, that the bismuth in the colon caused some retention of the bismuth in the stomach, and it therefore seemed unwise to continue the procedure of noting both the colon and stomach at the same time.

It was plain in some of the gastroptosis and splanchnoptosis cases that the method of estimating the rate of transit through the intestine to the ileocecal valve to be six hours, and the time for its accumulation in the descending colon, sigmoid and rectum to be twenty-four hours, should be modified. Seven of the cases in which the bismuth was localized in the cecum and proximal transverse colon at the end of the twenty-four hours showed no diseased condition in the colon other than atony and neuromuscular dilatation. From the plates of these cases the belief seemed warranted that the rectal-injection method for outlining the colon and studying its anatomy is better than the method by mouth in which the making of observations at intervals of six hours or more to note the transit of the bismuth is used. That is, in so far as the colon is concerned, upward transit of bismuth is generally a better means of studying the motility and stricture than is the use of bismuth from above, although an occasional case could be diagnosed by the descending instead of the ascending bismuth.

The winter added three cases in which ulcer was seen pitted with the bismuth. Against these three, twenty-seven were diagnosed as gastric or duodenal ulcer, gastric ulcer being found twelve times. Of the fifteen remaining all were duodenal ulcers but one, which was a mass of adhesions in which a cause could not be figured out satisfactorily. In two of the duodenal ulcers, gastric ulcer was also present, and in one of the gastric a duodenal ulcer was found. The twenty-seven patients were all operated on, those not operated on not being reported. In the cases of duodenal ulcer the diagnosis was best made by the history and the laboratory methods rather than by the x-ray method, which in my experience was too fallacious for accurate diagnostic deduction.

Carcinoma of the stomach was best diagnosed by the x-ray method, for by it four cases were diagnosed early enough for complete excision and expectation of a cure; in none of these was the history, test-meal or other laboratory methods of so much value. In the late cases either or any combination of methods sufficed.

Adhesions of the colon were best diagnosed by the x-ray method, there being no laboratory findings to take its place. An occasional case of gall-bladder adhesions was diagnosed by x-ray, but this method could not be depended on as could the history, examination and an occasional suggestive test-meal leading to the diagnosis of cholelithiasis or chronic cholecystitis. In chronic appendicitis the x-ray was almost valueless, the history and examination methods still being the best. Lane kinks were so commonly met with when taking x-rays in the Trendelenburg position that it is now doubtful to me that they have the surgical significance Mr. Lane placed on them. In only nine of the 167 cases in which they were noted could they be proved to be factors in causing delay at their site or above it in the stomach. Further, in the 200 or more laparotomies which I attended during the winter in which Lane kinks were searched for, the characteristic kinks were present in at least 90 per cent.; the same was true of the lesser number of necropsies performed.

Four cases of renal stone were encountered in which the renal calculus was not suspected from the history; in most cases in which this condition was suspected from the history and urine findings, renal stone shadows were seen in the kidney substance, pelvis, or ureters. When in the latter, all of them showed the stoppage of the transit of the stone at the brim of the pelvis or just short of the bladder. One case in a series of plates showed definitely what looked like a calculus in the pancreatic duct; operation proved it to be a calcified gland outside of and near the head of the pancreas.

126 East Sixtieth Street.

# THE TREATMENT OF PARALYSIS OF ANTERIOR POLIOMYELITIS

HENRY W. FRAUENTHAL, M.D.
Physician and Surgeon-in-Chief of the Hospital for Deformities and Joint Diseases
NEW YORK

Laymen, and some members of the profession, accept a statement made by Dr. Simon Flexner of the Rockefeller Institute, New York City, that no treatment is available at the present time for anterior poliomyelitis, as referring to the subsequent paralysis, whereas, Dr. Flexner is referring to the inflammation in the cord. It has been the means of deterring parents from making an effort toward treating the paralysis occurring in their children. What Dr. Flexner wished to convey in his remarks was that as yet nothing was known to arrest the inflammation in the cord and prevent the paralysis occurring before paralysis appears.

Fig. 1.—Case 1. Perfect recovery after treatment by high-frequency current, massage and muscle education.

Fig. 2.—Case 2. Disease began at 1½ years; treatment, 14 years later; recovered function in face and arm in 6 months.

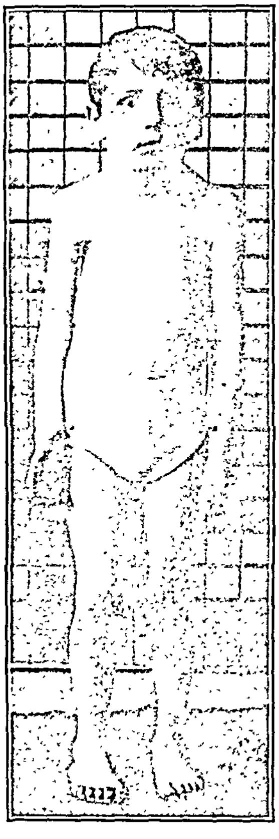

Fig. 3.—Case 3. Recovered function in arm and legs with treatment by electricity and massage, etc.

What can we do to bring about the best return of function in the muscles affected by the paralysis? What should treatment consist of? The treatment herein presented consists of the use of electricity, massage, hydrotherapeutics and muscle education, in which there is a mental concentration to guide the muscle effort.

Space will not permit of the description of splints either for prevention of deformity or aiding motion.

## ELECTRIC TREATMENT

After an extended review of medical literature, I have failed to find any detailed descriptive method of the use of electricity and massage in infantile paralysis, so I shall describe what I consider to yield the best results. When should electric treatment begin, and what form of current should we use? Many writers advise waiting from four to six weeks after the temperature becomes normal before doing anything in the way of treatment. According to the rules of the department of health of the city of New York, six weeks' quarantine is required. I have found that we obtain the best results by beginning when paralysis appears and even before the temperature is normal.

I have found, in the application of the Oudin or high-frequency current in cases of obliterating endarteritis, that the skin became blanched and remained so for several minutes, showing that the primary effect of the high-frequency is a contraction of the blood-vessels. With this effect in view, hoping to reduce the blood- and serum-compression on the nerve-cells in the spinal cord, I have, in the first few days of the paralysis, applied this current along the spinal column and feel positive that I have relieved the compression in the cord and hastened recovery.

Through the experiment of the United States government physicians in the Philippines, we have discovered that the high-frequency current materially destroys bacteria in water and also destroys their toxins. Hence we may conclude that it has a beneficial effect on the inflammation in the cord, in addition to its mechanical contraction of the blood- and lymph-vessels. When the temperature is between 98.5 and 99.5 F. and in some cases in which high temperature continues for several weeks, I have not let this deter me from treating the patient.

I give to the muscles involved a sinusoidal current, alternating with a combined galvanic and faradic current that contracts seventy-two times to a minute, synchronous with the heart-beat; and I regard this as an aid in the effect. It is known that contraction of the muscle can be obtained by means of an electric current when none can be obtained by the will; hence, this is a valuable means of retaining and developing the muscle fiber until it comes under the guidance of the mind.

Although many differences of opinion prevail as to the application of the sponge electrodes, I am in the habit of applying them at the origin and insertion of the muscle or muscle-groups involved, always laying stress on the importance of approximating the origin and insertion of the muscle as nearly as possible. For instance, in treating the peroneal group, these muscles being most frequently involved, one sponge is placed over the middle third of the outer side of the fibula, the foot flexed as much above a right angle as possible and the other sponge applied over the insertion of these muscles on the outer side of the foot. In this way, the bellies of the muscles are relaxed and a contraction is made more easily.

I believe that much foolish stress has been laid on the reaction of degeneration and I wish to prove, from a large practical experience, how deceptive it may be. It is said that a failure to obtain a muscle contraction by a galvanic or faradic current is an evidence of degeneration of the muscle fiber and that no improvement can be looked for in this paralyzed condition in the future. Do we fail to obtain a contraction in most cases? No! We find that the cutaneous surface will not tolerate the pain of the current and we must desist before contraction takes place, for most of the cases occur in children under 5 years of age, who see no reason for enduring the electrical pain. This is even true in other cases, when the age of the patient and his cutaneous tolerance are greater; the strong current may give no reaction and still reappearance of function may occur. Hoffa always cut down on the muscle to determine its character.

The strength of the currents used should be the weakest that will produce a contraction, and it is never to be used after contraction of the muscle ceases, nor longer than from two to three minutes on any particular muscle group, or from six to twelve minutes on the body at one seance. If this method is followed the child will not cry from pain, or have its nervous system upset by too long-continued electric treatment. I regret to state that the worst results seen by me have been in children of physicians who have had an excess of treatment; that is electricity given from one half an hour to an hour daily has inhibited the recovery and eaten up, as it were, all of Nature's element of repair.

Strychnin may be given internally or a solution used on a sponge and introduced locally, to increase the contraction of the muscle fibers.

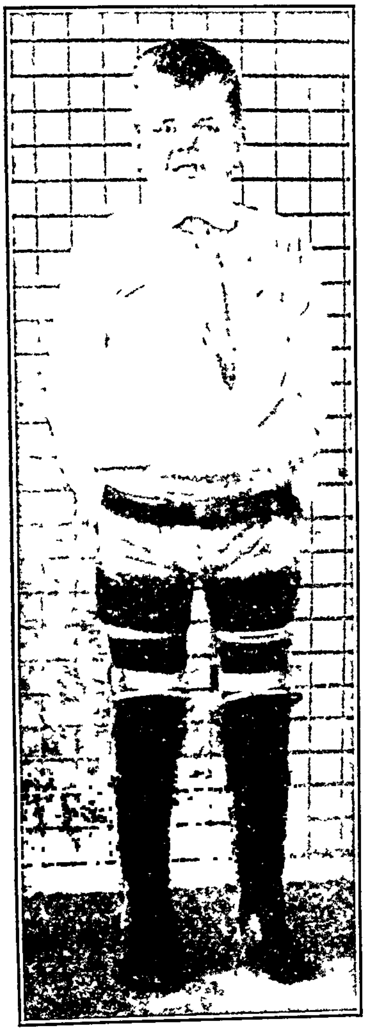

Fig. 4.—Case 4. After three months' treatment, able to stand alone with braces.

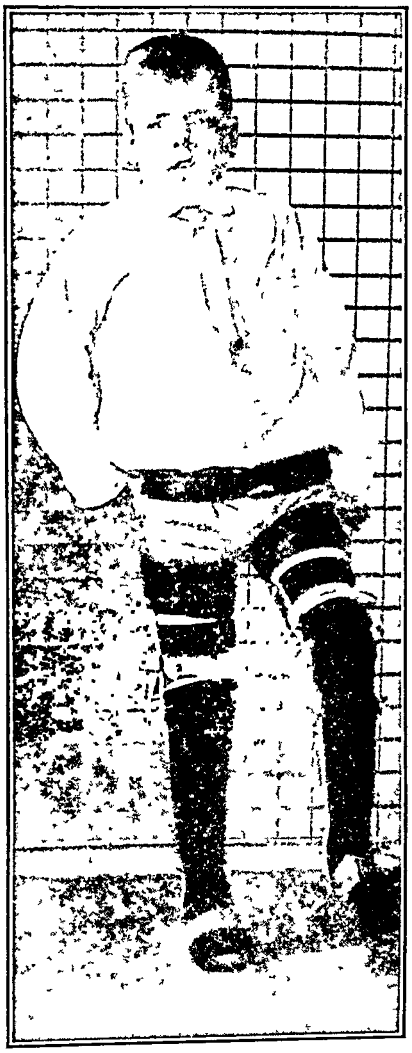

Fig. 5.—Case 4 Patient can lift leg at an equal angle or right angle.

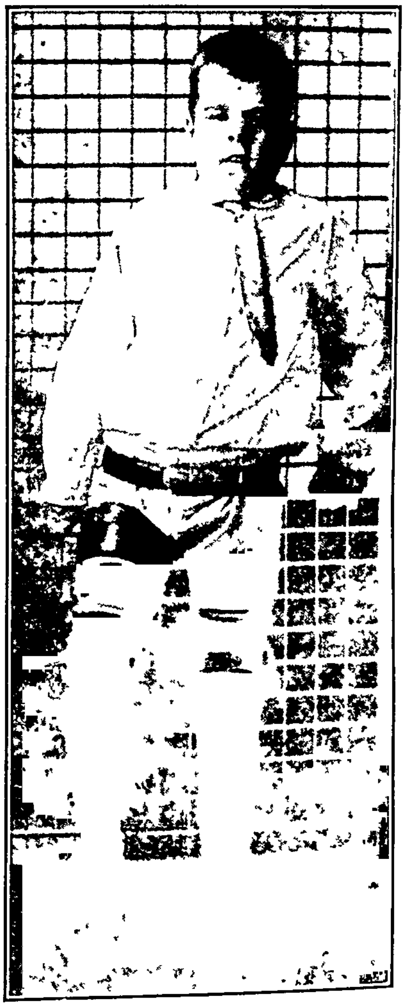

Fig 6—Case 4. Patient can lift right leg to right angle.

### MASSAGE

Dr. Benjamin Lee[1] says: "In the essential paralysis of infancy, truly wonderful results are obtained by massage." Massage treatment should be entered on the moment the acute inflammatory symptoms have disappeared and be continued daily in the face of seeming absolute ineffectiveness, for weeks and even months. Cases in which no improvement can be detected for long periods often suddenly begin to improve and progress with great rapidity.

The effect of massage may be classified as follows: mechanical, reflex, thermal, electrical.

---

[1] Lee, Benjamin: Hare's System of Practical Therapeutics, ii, p. 321.

1. The mechanical effects are by far the most important, but the others should not be overlooked or forgotten. They consist of the interchanging of cell contents under the influence of alternate pressure and relaxation; a quickened movement of the blood in the capillaries, especially in the muscular tissue; increased activity in the movement of the areolar fluid; acceleration of the currents of both blood and lymph in their respective channels.

2. The reflex or purely nervous effects of massage are obtained by light stroking and percussion. The former produces results which can only be explained on the supposition that it acts as a stimulant to the reflex system of nerves, the force used not being sufficient to account for any change on the mechanical theory.

3. The thermal effects of massage and movements are almost too apparent to need scientific demonstration; everyone is familiar with the fact that both muscular contraction in the form of ordinary exercise and simple friction develop bodily heat in a striking degree. Dr. Weir Mitchell, in his essay on "Fat, Blood and How to Obtain Them," notes (what has been observed by many others) that he has frequently seen the strangely cold limbs of children suffering with infantile paralysis gain from 6 to 10 degrees F. during the massage.

4. The electric effect of massage results partly from the development of the surface heat, partly from the surface friction, partly from the attrition of the muscular fibers and cells, and partly from the nerve stimulation and chemical action.

Graham observes that muscles give a much more ready, vigorous and agreeable response to the will and to the faradic current after massage than they did before.

A child suffering from infantile paralysis was introduced; the affected limb having a surface temperature of 70 F., the poles of a battery were applied to a limb, and 11 milliamperes were required to produce muscular contraction; the limb was then massaged and the temperature was found to have risen to 95 F.; the poles being applied at the same points, contractions followed the employment of only 5 milliamperes. It is evident, therefore, that massage diminishes the resistance of the tissues to the electrical current and increases the electrical contractibility of the muscles.

As some men prominent in orthopedics and neurology have condemned the use of electricity and massage, I have taken one of the most recent articles, as illustrative of this side of the subject; that is, Dr. Henry Ling Taylor[2] says: "The conventional treatment by electricity and massage is completely ineffectual." To support this position, he continues: "This was publicly acknowledged to Dr. Bernard Sachs of New York, a distinguished neurologist, etc., and chairman of the Collective Investigation Committee of the New York epidemic of 1907, at the Congress of American Physicians and Surgeons, at Washington, May 10, 1910. In these words he spoke of electricity and massage: 'I consider that the time given to massage and electricity, in these cases, is time wasted. I cannot see that these same methods do any definite good.'"

It is true that Dr. Sachs made the preceding statement in May, 1910, as I was present at the time; but five months later, on Oct. 24, 1910, at the New York Academy of Medicine, Dr. Sachs,[3] in discussing this subject, spoke of electricity and massage in the highest terms, as he had previously done, thus showing that a man of the highest standing, from a later and more comprehensive knowledge of the subject, completely changed his views of the value of electricity and massage—a striking illustration of the old adage, "Wise men change their minds."

Dr. Taylor's unconscious accord with this view is shown on the next page in his own article, where he speaks in the highest terms of vibration (which is a simple mechanical massage) and active and passive movements (which have always been classed under Swedish massage).

The abuse of treatment is found in prolonged massage. Children who receive an hour or more treatment daily cannot improve in the face of such a physical tax. I have seen many cases in which the overtreatment has deterred the progress of recovery. Fifteen to twenty minutes is sufficient treatment to administer daily.

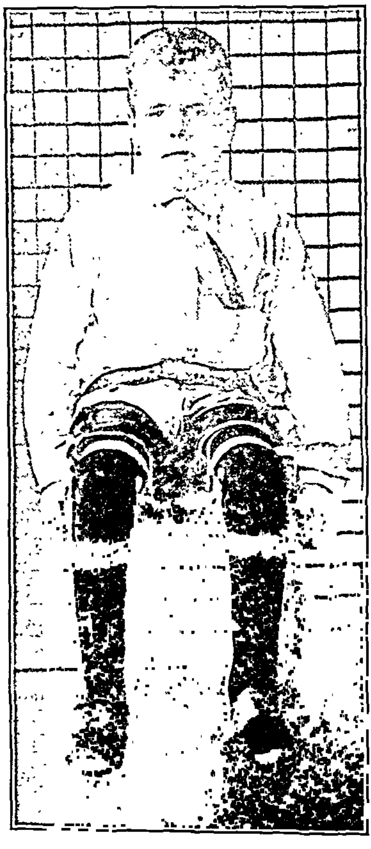

Fig. 7.—Case 4. Patient bearing weight on braces.

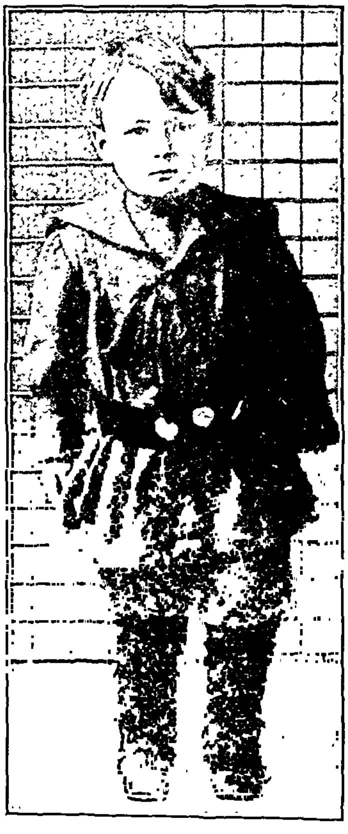

Fig. 8.—Case 5. After one year of massage, electricity and muscle education, patient is able to walk with almost normal gait.

### HYDROTHERAPEUTICS

The use of the bath, whereby we may float the limbs and aid motion, is a valuable adjunct in treatment. I wish to draw attention to the value of immersion of the affected limb in warm water from 95 F. to 102 F. for twenty minutes each night, in which we find that the

[3] Sachs, Bernard: Treatment from the Neurologist's Viewpoint, in a Symposium on the Treatment of Acute Anterior Poliomyelitis, THE JOURNAL A. M. A., Oct. 22, 1910, p. 1465.

62½-pound pressure of the water when removed to the atmospheric pressure of 15 pounds to the square inch results in a dilatation which, together with the heat absorbed, produces an effect on the trophic centers and improves the temperature and growth of the limb. The paralyzed limb retains this heat for hours.

### MUSCLE EDUCATION

Finally, I wish to call attention to a class of active and passive exercises done before a mirror, having the patient concentrate his mind on the affected muscles. When the origin and insertion cannot be approximated by an effort of the will, the attendant aids in the effort.

After a time it is found that the motion may be brought under the control of the will. It is known that when motion is guided by mental concentration, the sulci in the gray convolution in the brain presiding over this motor area are increased, as well as the caliber of the nerve going from the cortex to the periphery. It has been demonstrated by Anderson, of Yale, and others, that when a person is securely placed on a body balance and concentrates his mind on an extremity, the hyperemia thus produced tips the body balance in the direction of this limb.

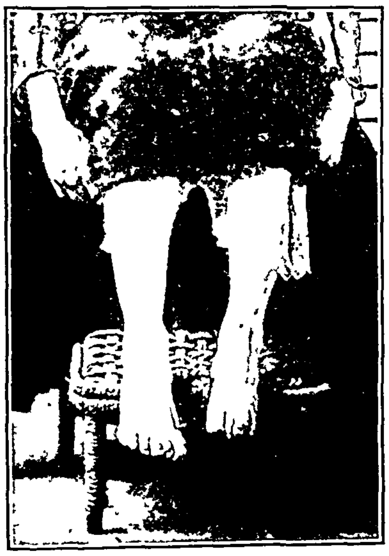

Fig. 9.—Case 6. Recovery after 20 years' daily treatment, massage and electricity by motion.

Figs. 10 and 11.—Case 7. Result of severe attack of infantile paralysis.

A moment's thought makes clear the fact that the nerve efficiency or nervous control as displayed by the gyrations of the nautch dancer can be developed by any person in any set of muscles if a proper effort is made for development of sufficient nerve force and nerve control. The stimulus transmitted from the brain to the periphery depends on the caliber of the conducting nerves, as the diameter of copper wire regulates the volume of electric current capable of transmission. We must now realize that the concentration of the mind on the muscular effort not only initiates the movement, but also determines blood to the controlling nerve centers, producing growth and development in the conducting filaments.

In this treatment of infantile paralysis, in addition to the application of massage, the treatment by the galvanic, faradic, sinusoidal, and high-frequency electrical current, in children over 3 years of age, a course of muscle education before a mirror is added, which I regard as one of the most important in its treatment, because recovery is best brought about by the action of the will, influencing action after massage and electricity have brought the muscle under the control of the mind.

The muscles most frequently involved in infantile paralysis are the peroneal group, and the plan of exercising one set of muscles can be utilized in another set of muscles involved. Placing the child in a chair before a mirror in a comfortable position, I first approximate the origin insertion of this muscle group by bringing the foot up to a right angle with the leg, and then urge the child to aid in bringing up the little-toe side of the foot through an arc of about 30 degrees. If the muscle contraction is such that the child cannot do this alone, the instructor places one hand on the knee to keep the leg in the position, and places the other hand under the foot, which greatly aids the efforts of the child in producing the required contraction. This should be repeated several times, but not to the point of overtiring these weakened muscles. Each set of muscles should be contracted in a similar manner. If the motion cannot be brought about, still the mental effort should be made for the attainment of this action.

To realize how efficient this method is, I wish to state that through this, combined with other treatment, I have been able to show at medical meetings some forty-three patients practically cured, who were unable to walk for periods extending from nine months to four years, having received some form of treatment during this time by other physicians, and having been referred to the Hospital for Deformities and Joint Diseases by such able observers as Kerley, Koplik, Mandl and many others.

It has been learned from necropsy that when areas in the brain have been destroyed by tumor or cysts, the function for this area has continued, and by the decussation of the nerves other areas in the brain have taken up the function. I am of the opinion that in cases in which recovery has taken place in paralysis, after a few years, the motor conduction from the brain to the periphery has been conducted through other motor tracts in a new circuit, passing around the damaged area in the cord.

### REPORTS OF CASES

Case 1.—Gertrude G., aged 6, normal delivery; previous history not pertinent. I was called by Dr. Brainglass to confirm his diagnosis of infantile paralysis on June 13, 1910. Sister of the patient had also had the disease. When I saw this child both legs were involved; the paralysis extended up the spine, and seemed to be of the progressive type. Hoping to stay the advance of the paralysis and expedite a recovery, having explained to the doctor the benefit I hoped to obtain by the d'Arsonval current, and receiving the concurrence of the family, I had the child removed to the Hospital for Deformities and Joint Diseases, where, after the first two days' treatment with high-frequency current along the spine, a marked improvement in the child's condition was shown. This treatment was kept up and combined with the other treatment of massage and electricity as herein described.

The child has made an almost perfect recovery; can bear her weight and hop on either leg, and walks with a normal gait. Several other patients have been thus treated.

The following case is shown to correct two long-standing fallacies: one, that no improvement will occur, whether spontaneous or under treatment, after one year; the other, that after failure to react to either the galvanic or faradic current, known as the reaction of degeneration, no improvement can be looked for.

Case 2.—Frank S., boy, aged 16, when 1½ years old had an attack of infantile paralysis involving his face and right arm. Fourteen years after this attack he appeared at the hospital hoping to receive treatment that would improve the condition of his face. The right side of his face was paralyzed, and he could not close his right eye in the least. He was turned over to Dr. Charles Rosenheck, who had had five years' experience at the Roosevelt Hospital Dispensary, under Dr. Starr (department of neurologic diseases), and who reported to me that he was satisfied that his reaction of degeneration was such as to be beyond all hope of the slightest benefit. I requested the other members of the staff to confirm this condition, as I wished to see if, after the lapse of fourteen years, with a positive reaction of degeneration, any improvement could take place. The improvement was so great after being under constant treatment for six months (the boy being able to close eye and produce wrinkles in his forehead, with a return to the normal outline of the affected side of his face) that he was shown at the pediatric, neurologic and orthopedic sections of the Academy of Medicine of New York City.

Many other similar cases have been encountered.

Case 3.—This patient was referred to the hospital by Dr. Koplik, seven months after initial paralysis. When admitted, all the muscles were flaccid; child had no use of arms or legs; all muscles of respiration, including diaphragm and muscles of neck, were involved.

Under massage and electricity, the muscles of both legs have regained their normal function; nearly all function has returned to the left arm; function of the right deltoid is absent. but the trapezius and flexors of the hand have regained their function. There has been some atrophy of the pectorals and apparently some of the intercostal muscles, as shown in the picture.

When the child was admitted to the hospital we looked forward to obtain a necropsy. The extreme condition of this child makes the amount of recovery almost remarkable.

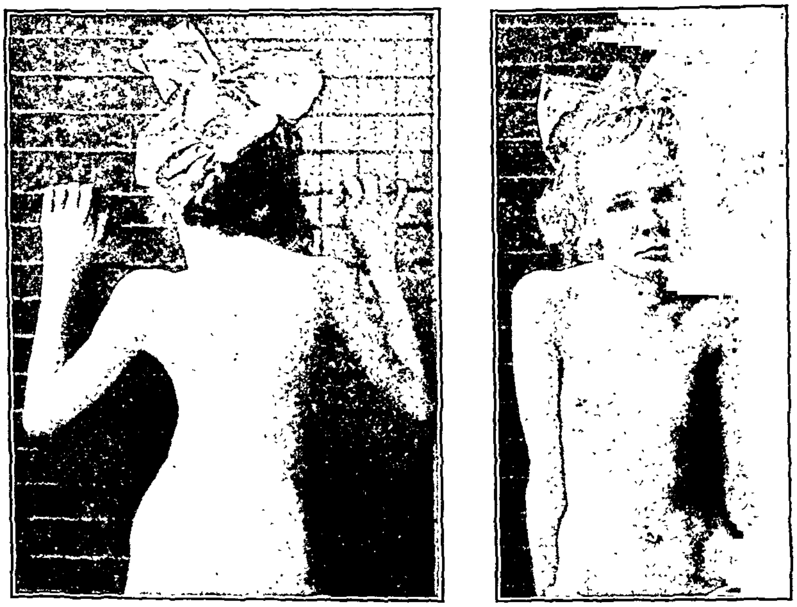
The following case represents a type of recovery partial in the one leg, with promise of a flail leg in the other:

Case 4.—Paul E. was seen in consultation and referred by Dr. Charles G. Kerley on Oct. 16, 1910. No spontaneous resolution had taken place in the right leg, and apparently from his muscular condition he gave no promise of improvement, while the other leg had very little ability to perform the normal motions, much less bear his weight.

The child had been ill since the end of July, 1910, with no spontaneous resolution; very little was looked for in the way of improvement. With Dr. Kerley's concurrence, the patient was removed to the hospital. As shown in the picture, after three months' treatment, he is able to stand alone in braces; is able to lift both limbs, at an equal or right angle; bear the additional weight of the braces, and I am looking for progressive improvement.

Case 5.—Arthur H., after initial attack, received four months' treatment at one clinic, eight months' treatment at another clinic, and on going to the third clinic, an operation for fixing the foot and ankle was suggested, as apparently there was extensive atrophy and no function.

At that time the patient's mother met the mother of another patient, who had had her child for treatment at the second institution for three years, with no ability to stand or walk, and who informed Mrs. H. that under treatment at the Hospital for Deformities and Joint Diseases for five months the child was able to walk without braces. Mrs. H., regarding this as an absurdity, made a special visit to this child's home, and seeing what she regarded as a miracle, brought her own child to the hospital.



Figs. 12 and 13.—Case 7, showing improvement after one year's treatment. Treatment by traction on extremities and head with daily electricity and massage to muscles.

This child was under treatment for seven months before he gained any promise of bearing his weight on his right leg, and after one year he is able to walk with almost normal gait.

The following case is shown to illustrate how massage and electricity, carried out by the parents alone, has won success, when many prominent physicians, who were consulted from time to time, made the darkest prognosis, with no promise of the use of either limb:

Case 6.—Olive B., when 1½ years of age had an attack of infantile paralysis, with both limbs involved; patient was not able to bear her weight on either limb for two years. During this time, various physicians were consulted, and the mother was told that the case was hopeless. At the advice of an old physician, the mother herself purchased a battery and gave the child massage and electricity. At a later time, braces were ordered by institutions and applied, but as the mother thought that this did not aid in the recovery, they were discarded.

Nevertheless, the mother proceeded in the massage and electricity, keeping up the treatment almost daily for twenty years. The girl is now 24 years of age, has no difference in the length of her legs, but the right foot is 1½ inches shorter than the left. She is just recovering from a corrective operation on this right foot.

I am particularly pleased to demonstrate through this case how much can be done through the affectionate perseverance of a parent, recognizing the improvement derived from the treatment, in opposition to the advice of many physicians that she consulted, also the advice she received in a number of institutions.

Case 7.—M. T., referred to the hospital by Dr. Reginald H. Sayre, who took the original photographs, suffered from a severe attack of infantile paralysis in the epidemic of 1907. The original diagnosis, from pain, was regarded as one of rheumatism, and this diagnosis was confirmed by consultants. Her total paralysis was not noticed until two weeks after the original attack. After six months she was referred to an orthopedic specialist and she journeyed from Yonkers to New York once a week to receive treatment, which consisted of electricity. The journey back and forth completely exhausted her for twenty-four hours.

The curvature in her back became so pronounced that a brace was applied. The deformity progressing, another consultation with a second orthopedic surgeon was requested. As a result of this consultation a Calot jacket was applied; she was also wearing a brace on her right foot. No improvement was noticed.

Consultation with a third orthopedist was sought. This orthopedist endorsed the treatment as conducted.

In September, 1909, she was seen in consultation by Dr. R. H. Sayre. Her condition then is shown in Figures 10 and 11. Since her case was regarded as one that should receive aggressive treatment, she was turned over to me, at the hospital, where for three months traction was made on her extremities and head, with daily electricity and massage to her weakened muscles. This was followed by a plaster jacket and jury-mast.

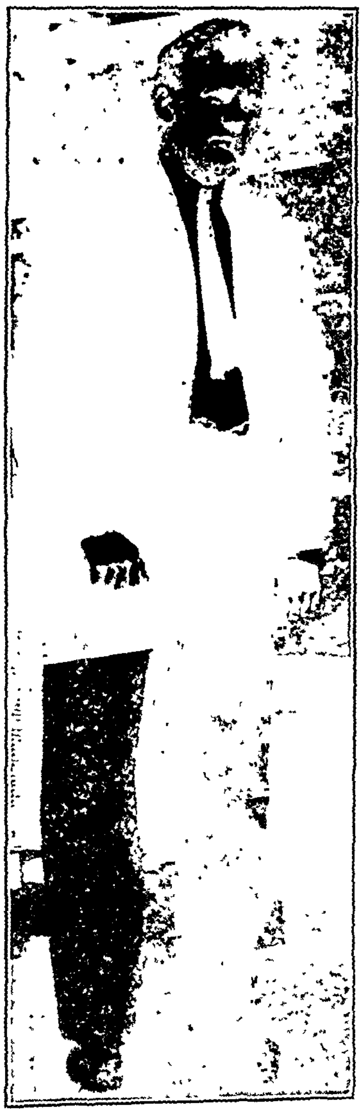


Fig. 14.—Case 8. Total paralysis 1½ years; recovery after 6 months' treatment with electricity, massage, etc.

Photographs taken one year later, as shown in Figures 12 and 13, show marked improvement, also demonstrate the fact, not accepted by many orthopedists, that in rotary lateral curvature, with bony deformity, much improvement can take place. A line drawn from the left nipple in the front, or from the angle of the scapula in the back, or following the crease of buttocks up, will bring out the change that has taken place.

Since these photographs have been taken, the patient has made decided improvement, but objects to having another

Case 8.—John D. R.: After a total paralysis lasting one and a half years, under the methods herein described, the patient obtained control of his legs and arms and is now able to get about, after four months' treatment.

Case 9.—George and Richard C., brothers, were afflicted with infantile paralysis during the summer of 1911 while in an isolated home at Glen Summit in the Pennsylvania mountains. The cases were referred to me by Dr. Charles Gilmore Kerley of New York. Richard, having a milder attack, made almost perfect recovery except the anterior and posterior tibialis, and peroneal in one leg. George had paralysis involving all the muscles of his body, and including thorax and vocal cords. One could distinguish his voice only by placing the ear to his mouth.

I am simply reporting this case to show that treatment continued for several years will bring about progressive improvement, for since the paralysis, the patient has gradually regained control of one group of muscles after the other, and although he still has light braces to aid his leg motions, he is able to go about without them.

The case also demonstrates the danger of permitting nurses and others not familiar with the care of these cases and the value of confining their efforts to the weaker muscles, to instruct the patient in the general setting-up exercises. For a period of over two years, George gave no evidence of spinal curvature or rotation. The case was turned over to a nurse who devoted her efforts to develop both sides, with the results that the stronger side was developed so much quicker than the weaker side that after a period of a few months a very decided lateral curvature was developed, which it will be difficult to correct.

Case 10.—Harry H., patient of Dr. Eagen of Brooklyn, had infantile paralysis involving all the muscles of the body, and under treatment of massage and electricity, made a perfect recovery of his arms and legs. His erector spinae muscles were so extensively involved that a right high dorsal lateral curvature developed. Under special care by devoting all the efforts to the weaker muscles, by electricity, massage and more particularly muscle education, this lateral curvature has been corrected.

I am simply calling attention to the preceding case to show that when all efforts are directed toward the weaker muscles and the stronger ones are allowed to atrophy, a muscle balance can be developed, but when bilateral exercises are attempted we have deformity in the limbs and lateral curvature develops in cases in which the spinal muscles are involved.

# THE PRACTICAL IMPORTANCE OF INFANTILE KIDNEY IN RENAL DIAGNOSIS *

J. T. GERAGHTY, M.D.,

AND

H. W. PLAGGEMEYER, M.D.,

BALTIMORE

The different varieties of kidney anomalies have been so thoroughly catalogued, and the classification so often repeated by various authorities, that the profession has come to be more or less conversant with their existence.

We wish to describe here a type of kidney not usually included in these classifications, which, when present, is of vital importance to the surgeon, as it may easily pass unrecognized if ordinary methods of examination are used. The particular anomaly to which we refer is the condition in which a large, hypertrophied kidney exists on one side and an infantile kidney on the other, the

---

* From the Genito-Urinary clinic of the Johns Hopkins Hospital.

urine from the deficient kidney, with all chemical and microscopic methods of diagnosis, appearing entirely normal. The concentrating power of the kidney is also normal. The quantity of urine secreted, however, is so small and the function so decreased, that this kidney alone may be insufficient for life. On examination, the kidney is normal in shape, color and consistency. On section, the general architecture is normal and microscopic examination shows normal tubules and glomeruli. It differs from the normal kidney in its diminutive size only. While a search of the literature reveals a comparatively small number of cases in which nephrectomy has been performed unwittingly on the larger kidney with disastrous results, the condition is, nevertheless, probably much more common than the number of reported cases would indicate.

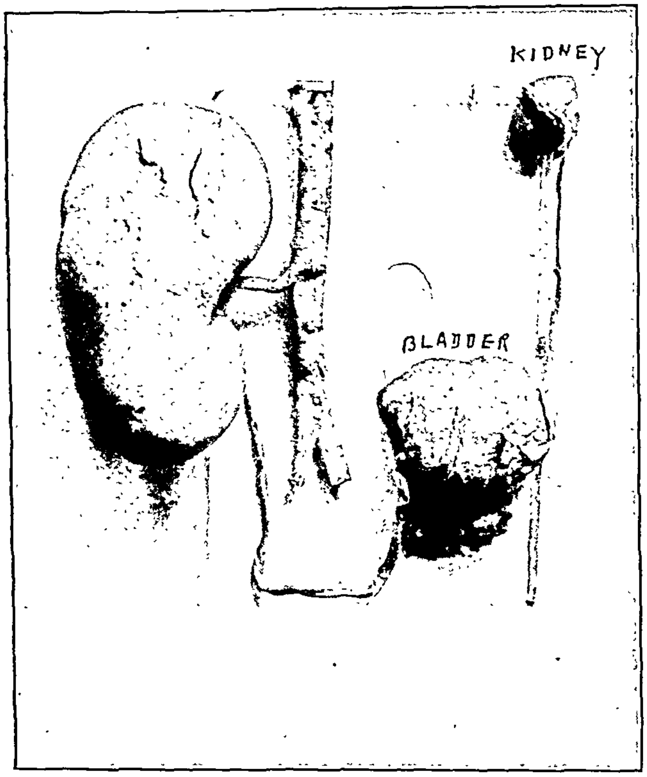

Fig. 1.—This kidney is an example of hypoplasia and the picture is inserted to show the contrast between hypoplasia and the infantile type.

Papin, in a very complete consideration of all possible kidney malformations, mentions briefly the type of organ to which reference is here made. He describes such an organ as secreting a urine, normal in every respect, except that the amount is very small. He mentions specifically that such a kidney may even have a high urea concentration. L. L. McArthur[1] reports a case in which he had performed nephrectomy for tuberculosis, which was followed by death from renal insufficiency and at necropsy a kidney, which he terms "infantile," was discovered. The ureters in this case had been catheterized previously and a perfectly clear, apparently normal urine obtained from the insufficient kidney. He also expresses the evident hopelessness of being able to diagnose this condition before operation.

The frequency in general of kidneys atrophic through various causes is seen from a study of 3,940 necropsies from the pathologic department of the Johns Hopkins Hospital. Among this number thirty-six cases of atrophy from various causes were found. Of these only six were unilateral, and of these six three belonged to the infantile type to be described. In this tabulation the moderate bilateral diminution in size found in some cases as a result of chronic nephritis was naturally omitted.

A study of statistics shows that there is excessively small probability of a person having only one kidney, the result of congenital absence or non-development. There is much greater risk of meeting with a deficient kidney of the infantile type. None of the statistics take into account those congenitally small or atrophied kidneys which weigh from 1 to 1½ ounces and which may possess some though not a full amount of glandular substance. Congenital aplasia and hypoplasia of extreme degree are practically the only types which are considered in the various classifications.

The material on which this study is based comprises three cases, obtained at necropsy in the pathologic department of the Johns Hopkins Hospital, one case from the Hunterian laboratory, two cases in which the condition was discovered at the operating table, and two cases diagnosed clinically as anomalies of this type.

Following is a description of the material on which our studies are based:

CASE 1.—Cat. In some experiments to determine how quickly the remaining kidney could take up the total function after nephrectomy, it was noted that the amount of urine decreased at once and the function dropped to one-fifth the previous amount, as tested by phenolsulphonephthalein.[2] This result was strikingly different from that in other experiments previously done, in which the remaining kidney almost immediately assumed a function equal to that of the two kidneys. The cause of the great decrease in function was revealed later by finding an extremely small kidney, which weighed only 6.4 gm. The kidney first removed weighed 26.4 gm. A careful microscopic and chemical examination of the urine from the small kidney revealed no abnormality.

The left kidney, the larger, measures 4 by 3.5 by 2.5 cm. The right kidney, the smaller, measures 2 by 2 by 1.25 cm. The capsules of the kidneys strip readily, leaving a smooth surface, on which nothing abnormal is to be seen. On section, the three zones of the kidney may be made out readily. The cortex. in the large kidney, measures 5 mm., and in the small kidney 2 mm., and nothing abnormal is to be seen in either case. Microscopically, the large kidney shows a histologic picture characteristic of the normally hypertrophied kidney. In

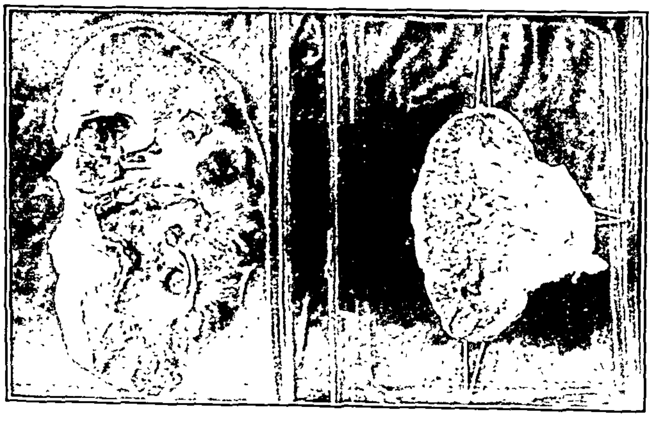

Fig. 2.—This is a kidney of the true infantile type. The section includes the lateral wall of the pelvis which gives the kidney the appearance of being hydronephrotic. It is unfortunate that the pyramids do not show in the photograph. With the naked eye the kidney is in every way normal.

[2] Rowntree, L. G., and Geraghty, J. T.: The Phthalein Test; An Experimental and Clinical Study of Phenolsulphonephthalein in Relation to Renal Function in Health and Disease, Arch. Int. Med., March, 1912, p. 284.

the small kidney, the picture is quite different. Definite scars may be seen, radiating from the arcuate vessels to the surface. These scars appear to be associated with the interlobular blood-vessels. In the scarred areas the tubules are atrophic or entirely gone, while here and there hyaline glomeruli may be seen. In the intervening spaces, both the uriniferous tubules and the glomeruli are normal in appearance.

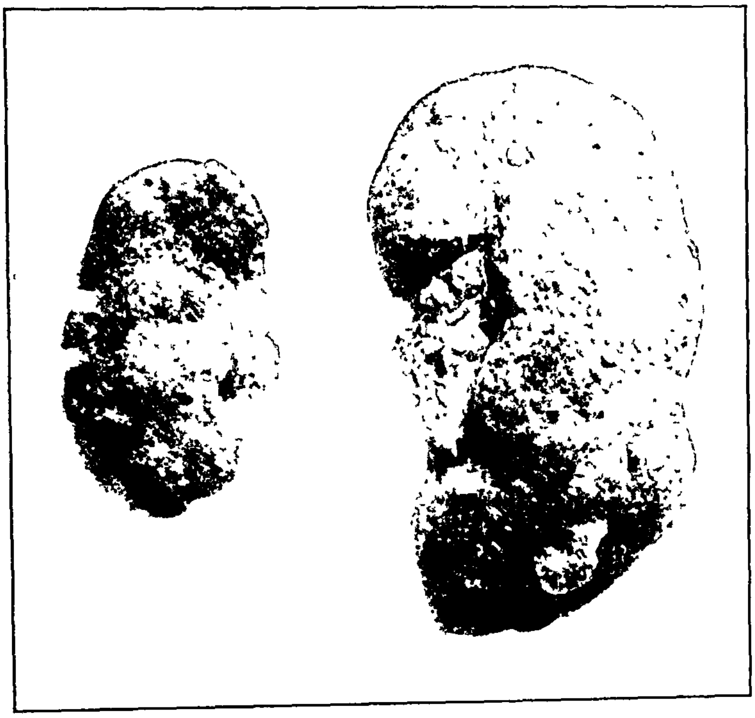

Fig. 3.—These are the kidneys described under Case 3.

Case 2 (Fig. 1).—Specimen in the Pathological Museum of the Johns Hopkins Hospital. The right kidney is enormously enlarged and measures 15 by 8 by 6 cm. The left kidney is extremely small and measures 3.5 by 2 by 0.75 cm. The capsules of both kidneys strip quite readily, leaving smooth surfaces. On section, the right kidney, aside from the huge size, shows nothing abnormal. The left kidney is very minute, and on section the architecture is partially obscured. Microscopically, sections from the right kidney show the usual findings in a kidney that has undergone compensatory hypertrophy.

Sections from the left kidney show that there is a minute amount of cortical tissue and only a few glomeruli are present The glomeruli that are present, however, are large and normal Associated with these glomeruli, and usually in their vicinity. are a number of normal convoluted tubules. The great mass of the kidney is composed of tubules, which look more like collecting than convoluted tubules.

Case 3. (Fig. 2).—*Diagnosis.*—Stricture of the left ureter and hydronephrosis of the left kidney; infantile kidney on the right.

M. T., woman, aged 48, admitted to the gynecological department of the Johns Hopkins Hospital (service Dr. H. A. Kelly), Nov. 13, 1912, with a history of attacks of pain in the left kidney region, accompanied by hematuria.

Examination showed a stricture at the lower end of the left ureter. The bladder urine was normal. Cystoscopic examination showed both ureteral orifices normally placed and normally functioning, the urine being perfectly clear. The patient refused treatment and left the hospital. Readmitted May 7, 1913, suffering with severe, acute nephritis, from which she died.

Necropsy No. 3935. The left kidney weighs 140 gm., and measures 10.5 by 5 by 3.5 cm.; the capsule strips readily and the surface shows a definite infarction and some small hemorrhages. The cortex varies from 1 to 2 mm. in width. On cross-section, the pelvis is markedly dilated, the dilatation involving the parenchyma and causing some pressure atrophy. The hydronephrosis was a result of adhesions (peri-ureteral) in the lower portion. The gross picture of an acute nephritis is also present.

The right kidney weighs 40 gm. and measures 5 by 2.75 by 1.25 cm. The cortex is 3 mm. in thickness. On gross examination, this kidney is apparently perfectly normal except for the changes, resulting from the acute nephritis present.

On microscopic examination the left kidney shows the usual picture of acute hemorrhagic nephritis, with added interstitial changes, the result of pressure atrophy. The right kidney, with the exception of the changes due to the acute nephritis, presents a picture of kidney tissue, normal in structure and architecture.

Case 4. (Fig. 3).—*Diagnosis.*—Chronic diffuse nephritis of left kidney; hydronephrosis and chronic nephritis in an infantile kidney on the right.

W. W., man, aged 70. Admitted Nov. 17, 1912, to Johns Hopkins Hospital, with hypertrophy of prostate. Death resulted from hemorrhage following prostatectomy.

*Necropsy.*—Right kidney measures 7 by 2.5 by 2.75 cm., and weighs 40 gm. The capsule strips readily, leaving a granular surface. Cortex is irregular in width, varying from 1 to 4 mm. The pelvis of the kidney is moderately dilated, but the papilli are not flattened. Microscopic section shows a moderate grade of chronic, diffuse nephritis, with a well-marked arteriosclerosis. The glomeruli are unimpaired, and the tubules are not replaced by fibrous tissue. The pathologic changes present in this kidney would not explain the diminutive size of the organ.

The left kidney measures 11 by 6.5 by 4 cm.; weight 180 gm. The capsule strips readily, leaving a granular surface. The cortex is irregular in depth and the pyramidal portion shows a definite increase in gray, translucent connective tissue. The pelvis is moderately dilated. The microscopic picture shows lesions similar to those on the opposite side.

Both of these kidneys are the seat of a typical, moderate grade arteriosclerosis, and the process is of about equal grade in each kidney.

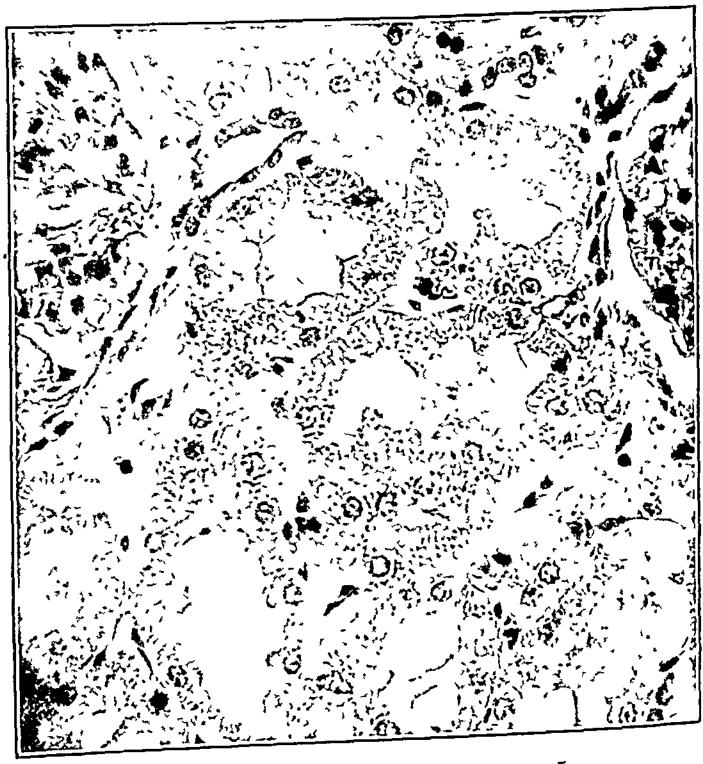

Fig. 4.—Microscopic section in Case 5.

Case 5. (Fig. 4).—*Diagnosis.*—Hypertrophy of left kidney, tuberculosis in an infantile right kidney.

T. C., man, aged 39. Admitted to Johns Hopkins Hospital May 16, 1910. The left ureter was readily catheterized, but on account of ulceration of the right ureteral orifice it was impossible to pass a catheter and the urine was collected transvesically for a period of one hour.

Results of examination:

| RIGHT KIDNEY | LEFT KIDNEY |
|---|---|
| 20 c.c. | 40 c.c. |
| Cloudy. | Clear. |
| Microscopic pus and tubercle bacilli. | Microscopically negative. |
| Specific gravity, 1.016. | Specific gravity, 1.020. |
| Urea, 1.7 per cent. | Urea, 2.8 per cent. |
| Phenolsulphonephthalein, approximate time, eighteen minutes. | Phenolsulphonephthalein, approximate time, four minutes. |
| Excretion, a trace. | Excretion, 44.4 per cent. |

At operation a small right kidney was found and removed by Dr. H. H. Young. The kidney measured 7 by 2.5 by 3.5 cm., and weighed 40 gm. The surface appeared normal, capsule was not adherent and the color was good. On palpation, the upper third seemed softer than usual, but the consistency of the remainder of the organ was firm. On section, the upper third of the kidney showed well-marked tuberculosis, between the pyramids and the cortex, with small cavity formations. The macroscopic appearance of the lower two-thirds is normal.

Microscopic examination of the kidney tissue in the lower two-thirds shows a slight diffuse increase in connective tissue, manifest about the glomerular capsule. The tubular epithelium is somewhat swollen and the general architecture is slightly blurred. In the non-tuberculous portion the pathologic changes present are extremely minute.

It is very evident that if, in this case, the disease had been in the hypertrophied left kidney, instead of in the infantile kidney, nephrectomy, if performed, would probably have resulted in death. The deficiency in this right kidney could not have been recognized, except through a functional estimation.

Case 6.—*Diagnosis.*—Tuberculosis of the right kidney; infantile left kidney.

W. B. S., man, aged 30. Admitted to the Church Home and Infirmary February, 1911, with a history of urinary symptoms of two years' duration. Tubercle bacilli were demonstrated in the urine. The prostate, seminal vesicles and epididymes were normal. The bladder was so contracted that ureteral catheterization was unsuccessful. The total renal function, estimated by phenolsulphonephthalein, showed an excretion of 36 per cent. for one hour. The definite reduction in the total function suggested the possibility of a bilateral lesion. A double exploratory operation was advised. The left kidney was first exposed, and discovered to be about one-fourth the size of a normal kidney. In every other respect the organ seemed normal. There were no perirenal adhesions; the surface was smooth and the consistency normal. The ureter showed no thickening or induration suggestive of tuberculosis. In view of the reduced total renal function and the presence of an infantile kidney on the left, it seemed probable that tuberculosis was present on the opposite side. If the hypertrophied right kidney was tuberculous it was also evident that nephrectomy could not be performed, because of the deficient kidney on the left. Consequently, the right kidney was not explored.

The patient was seen again in April, 1913. His general health had been fairly well maintained. The urine was quite cloudy from pus and the total renal function, as estimated by phenolsulphonephthalein, showed an excretion of 25 per cent.

This is a decrease of 11 per cent. since the previous examination. It seems probable that the tuberculous process of the right kidney is causing a decrease of the total function, because of the inability of the left kidney to undergo compensatory hypertrophy.

Case 7.—*Diagnosis.*—Tuberculosis of the right kidney; infantile left kidney.

Man, aged 27, admitted with urinary symptoms of ten months' duration. Tubercle bacilli were found in the urine. Catheterization of the ureters and estimation of function, the urine being collected for one-half hour, gave the following results:

| RIGHT KIDNEY | LEFT KIDNEY |
|---|---|
| 80 c.c. | 4 c.c. |
| Cloudy. | Clear. |
| Microscopically, pus and many tubercle bacilli. | Microscopically, negative. |
| Phenolsulphonephthalein, approximate time, five minutes. | Phenolsulphonephthalein, approximate time, ten minutes. |
| Excretion, 30 per cent. for one-half hour. | Excretion, 8 per cent. for one-half hour. |

In order to confirm the preceding findings, catheterization was repeated later with almost identical results. The total function, as estimated by phenolsulphonephthalein, showed an excretion of 35 per cent. for one hour, following intramuscular injection. Examination by Roentgen ray was negative for stone, but showed a kidney shadow in the left side, not quite half so large as the shadow on the right.

The normal character and color of the urine, the small amount secreted on the left side, the relatively high urea concentration and the small kidney shadow make the diagnosis of infantile kidney probable. Furthermore, the right kidney, although definitely tuberculous, still retained a function equal to or even greater than that of a perfectly normal kidney, which indicates that, previous to the onset of disease in this kidney, it was hypertrophic.

Case 8.—*Diagnosis.*—Double ureter and pelvis with hematuria on right side; infantile kidney on the left side. First seen August, 1912. Following a severe blow over the region of the right kidney the patient noticed blood in his urine which continued up to the time of the examination. The urine is of a distinct wine color, and, on cystoscopic examination, a stream of bloody urine is seen issuing from the right ureter. Catheterization of the ureters was performed and functional estimation made by means of phenolsulphonephthalein, the urine being collected for one-half hour.

Results of examination as follows:

| RIGHT KIDNEY | LEFT KIDNEY |
|---|---|
| Function free and rapid. | Function slow; about one-eighth the amount of that on right. |
| Bloody. | Clear, good color. |
| Microscopically, negative, except for red blood-cells. | Microscopically, negative. |
| Urea, 1.2 per cent. | Urea, 1.2 per cent. |
| Phenolsulphonephthalein, approximate time, five minutes. | Phenolsulphonephthalein, approximate time, five minutes. |
| Excretion, 35 per cent. for one-half hour. | Excretion, 4 per cent. for one-half hour. |

The preceding examinations were repeated three times, with practically identical findings on each occasion. Pyelography, using 15 per cent. collargol, showed, on the right side, a double ureter extending from the crest of the ilium and ending in two apparently normal pelves rather widely separated. Injection of 7 c.c. into the left kidney pelvis produced definite pain and pyelography showed an irregular, small, indefinite pelvis. Estimation of the total renal function was normal, there being an excretion of 50 per cent. for one hour, following intramuscular injection of phenolsulphonephthalein.

In this case, on the right side, which is the source of the hematuria, there are two separate kidneys, or more probably, a large bifid kidney, which has seven-eighths the total function. On the left side there is a kidney which secretes a urine small in amount, microscopically and chemically normal, and with a high urea concentration, which is equal to that of the right kidney. The function, however, is so low that it is extremely improbable that it could maintain life. The practical importance of recognizing the deficient kidney in this case needs no comment.

Of the eight cases described, a histologic study of the kidneys was made in five. In one case, the kidney was discovered on exploration, but no tissue was obtained for microscopic study. In two of the cases, a clinical diagnosis of the condition was made, but no exploratory opertion was performed.

A histologic study of the first two cases shows definitely the presence of pathologic changes. Over considerable areas there is an entire absence of tubules and glomeruli, these areas being represented by fibrous tissue. In other areas one finds perfectly normal tubules and glomeruli which could undoubtedly secrete a urine which is normal in general character. The changes present do not seem to be typical of secondary atrophy. The cause of the diminutive size in these two cases lacks definite explanation, although it seems probable that the changes are the result of prenatal disturbance. The kidney in Case 2 approaches true hypoplasia, and does not properly belong to the class of infantile kidneys, but has been included here because the normal tubules and glomeruli present could have secreted a urine normal in character and would offer the same difficulty in diagnosis, commonly present in infantile kidney.

In Case 3, the small kidney was normal in its general architecture, and the histologic changes present were only those of an acute nephritis. This kidney may properly be termed infantile because although the organ is diminutive in size, the architecture is normal.

In Case 4, both kidneys are the seat of a moderate grade of hydronephrosis as the result of back-pressure from the enlarged prostate and there is present also, in equal degree on each side, a moderate grade of chronic diffuse nephritis. The marked difference in the weight and size of the kidneys cannot be explained satisfactorily as being secondary to this evident pathologic process present in each kidney, as the amount of disease present would not explain the marked diminution in size on the right.

It seems probable that this discrepancy in the size of the two kidneys existed before the onset of the present pathologic process, because the left kidney, although the seat of chronic inflammatory changes, has a weight in excess of normal. This enlargement of the left kidney must have occurred before the onset of the present bilateral affection, for a kidney which has present in it a diffuse pathologic process does not undergo compensatory hypertrophy. Here the small kidney belongs to the infantile type and the diminutive size is not the result of secondary atrophy.

In Case 5, the tuberculous process was present in the upper pole, the remainder of the kidney being perfectly normal in architecture and general appearance. This kidney also belongs to the infantile type in that, although diminutive in size, the renal substance is entirely normal, except for occasional minute changes about the glomeruli. The smallness of the organ in this case is not the result of the tuberculous process, but the tuberculosis has occurred in a kidney congenitally small.

These five cases fall into two groups. In the first group, to which Cases 1 and 2 belong, a small kidney is present, which secretes a normal urine, but which is not truly infantile, in that the histology is far from normal. In the other class, under which Cases 3, 4 and 5 are grouped, the kidneys may truly be termed infantile in type. Of course the differentiation between these two types is of comparatively little practical importance to the operating surgeon, as the two present the same element of danger, in that they secrete a normal urine, but are deficient in function.

In two of these cases tuberculosis was present in the large, hypertrophied kidney, and in one the disease occurred in the infantile kidney. In a case like the last mentioned, the presence of this type of kidney cannot be diagnosticated with the present methods of examination. This, however, is of no practical importance. The danger to the surgeon of the infantile type of kidney is well illustrated by these two cases, in which the disease occurred in the larger hypertrophied kidney, and the presence of the deficient kidney on the opposite side can be detected by functional estimation only.

It is rather striking that the four infantile kidneys in which the weight was obtained were, in every instance, one-fourth the weight of the normal kidney. The three kidneys from man each weighed 40 gm. The uniformity in size and weight is noteworthy, and it is possible, that there may be an embryologic explanation of the condition. It seems quite apparent that these kidneys have not the power of compensatory hypertrophy, for with the decreasing function in the hypertrophic kidney, due to disease, there is apparently no attempt on the part of the infantile kidney to make up the deficiency.

## CONCLUSIONS

The diagnostic points in determining the presence of a kidney of the type presented above, may be summed up briefly as follows:

1. When disease is present in the larger, hypertrophied kidney, the total function, as estimated by phenolsulphonephthalein, is decreased, and the function of the diseased kidney is usually greater than the function of the supposedly healthy kidney.
2. The function of the infantile kidney shows marked decrease, although the urea percentage and general character of the urine is normal, while the amount of urine secreted is relatively small.
3. Pyelography is of doubtful value, since the size of the kidney pelvis is usually not a reliable index of the size of the kidney.
4. In persons not too stout it may be possible to secure Roentgen-ray shadows, showing the presence of a diminutive kidney. In Case 7 considerable diagnostic help was obtained from the Roentgen ray, which showed a very small kidney shadow, less than half that of the opposite side. This, taken in conjunction with the functional findings and the character of the urine, was of considerable diagnostic aid.

In conclusion, it may be emphasized that kidneys of the infantile type are a menace to the surgeon if the opposite kidney is the seat of the disease. The character of the urine may be normal in appearance and the urea concentration or percentage may be high. The recognition of this anomaly may be extremely difficult, and its presence can be suspected only when function estimations are carried out.

We are greatly indebted to Dr. H. H. Young for the opportunity of studying two of the cases here cited, and to Dr. A. Keidel for the privilege of studying Case 8.

330 North Charles Street.

**Presence or Absence of Hydrochloric Acid in Gastric Contents.**—It has been the experience of T. Gillman Moorhead (Dublin *Jour. Med. Sc.*, Oct. 1, 1913) that HCl is *almost* invariably absent in the vomited matter in cases of acute dyspepsia and in many chronic disorders of the stomach; also it is found subsequently to be present in a test meal washed out in the usual way. Frequently vomited matter is intensely acid to litmus paper, but as a rule this will be found due *to* the presence of organic acids. The explanation is that in acute troubles gastric secretion is presumably inhibited, abnormal fermentation takes place, and hence the absence of HCl and the presence of organic acids.

# HELIOTHERAPY WITH SPECIAL REFERENCE TO THE WORK OF DR. ROLLIER AT LEYSIN *

HENRY DIETRICH, M.D.
LOS ANGELES, CAL.

If we open our school text-books on materia medica and therapeutics we shall rarely find any mention made of the qualities or therapeutic uses of solar energy. We learn the properties and supposed uses of scores of drugs and yet when we enter on practice, we find that our reliable therapeutic armamentarium is really a limited one. Water, fresh air and that most powerful agent of all, solar energy, which is supplied to us everywhere, receive only secondary consideration. The study and use of light, both artificial and solar, however, following the excellent work of Finsen, have come into prominence.

The use of light as a therapeutic agent is very old. C. E. Rogers tells us that some years ago, while traveling in the tropics of Central America, he observed a peculiar custom among some of the Indian tribes. Occasionally he would see one lying naked on the ground for hours at a time in the fierce rays of the midday sun. He learned that this was their method of treating consumption and rheumatism. The custom is an old one, having been practiced before the Spanish invasion and can be traced all along the western coast of the South and North American continents. In the Old World Herodotus as early as 484 B. C. describes the sun-bath, and the Romans built solaria on their houses for the purpose of utilizing the sun's rays. It is then lost sight of therapeutically until toward the end of the eighteenth century, when it was used to treat cancerous ulcerations.

Finsen by his great work established many scientific facts and again brought the subject prominently before the medical profession, and established it as a clinical method. The French school under Bonnet and the surgeons Ollier and Poncet of Lyon observed and reported the good effects of heliotherapy in chronic joint-affections. The application of the method was at this time confined principally to the warm sunny climate along the Mediterranean, until Bernhard of Samaden, Switzerland, began using it on the high plateau of Graubunden. He first treated granulating wounds, and later extended its use to surgical tuberculosis and now gives the following indications for heliotherapy:

I. Wounds: (1) traumatic in which primary healing is not probable as in case of those caused by blasts or crushing injuries; (2) due to circulatory disturbances, as ulcus cruris, mal perforans; (3) burns and frostbites; (4) infected wounds.

II. Tuberculosis of the skin and serous membrane. Tuberculosis of the lymph-nodes, bones, joints and others.

III. Carcinoma of the skin.

IV. Specific ulcers with little tendency to heal.

V. Leukemia, pseudoleukemia, tuberculosis of larynx and lungs.

In 1903 Rollier established the first sanatorium for the systematic treatment of surgical tuberculosis at Leysin, Switzerland, and since then he has erected two more at the same place, so that he can now accommodate 450 patients. These sanatoriums are located respectively at altitudes of 1250, 1350 and 1500 meters (about 3800, 4100 and 4500 feet). Two hundred beds are reserved for children. It is his work, his method and his results that I wish to review.

Before discussing his technic and results, it may be well to mention some of the properties of light.

Light is a wave-like disturbance which passes out in all directions from a luminous object through an ethereal medium.

Waves of light are not all of the same wave length. The difference in length makes itself known to our eyes as color.

When the sun's rays pass through a prism they are dispersed or decomposed into several kinds of light, and this we call the visible solar spectrum in which it is customary to distinguish seven colors—red, orange, yellow, green, blue, indigo and violet. A sun-ray, therefore, is really a bundle of rays and these individual rays do not occur singly in nature.

The different colors of the spectrum then are due to difference in length of the light-rays. The red are the longest, the violet the shortest. Each light-ray has three properties, namely: (1) heat production, (2) light production, (3) a chemical action. The red rays are principally heat rays. Light is most intense in the yellow. The violet rays have principally a chemical action, and are often called actinic rays. On both sides of the visible spectrum are large fields which are invisible to the eye and therefore called the invisible spectrum, or area of the ultra-red and ultra-violet rays. The different rays of the spectrum and the invisible rays differ as to their absorbability and therefore in their action, as only those rays can produce an effect, which are absorbed.

### EFFECT OF LIGHT ON BACTERIA AND THEIR PRODUCTS

Downe and Blunt first showed that sunlight retards and inhibits the growth of bacteria. Dieudonné found that direct sunlight killed typhoid bacilli in one and one-half hours, daylight in eight hours, arc-light (800 candle-power) in eight hours and incandescent light in eleven hours. Arc-light is rich in ultraviolet rays. Tubercle bacilli are killed by the sun's rays in five hours at the seashore; in four hours at an altitude of 2,800 feet, and in three hours at an altitude of 5,000 feet. Diffuse light requires about double the time to produce this effect. This action is principally due to the chemical rays, though all rays have a bactericidal action. The ultraviolet rays also act on the ferments and toxins. Diphtheria toxin quickly loses its toxic property under the influence of these rays, while the antitoxin is less affected by them. Small-pox vaccine is but slightly altered by sunlight or diffuse light, but greatly so by ultraviolet light.

### ACTION OF LIGHT ON THE HUMAN BODY

This varies according to the intensity, the altitude and the individual. Sunlight in passing through the atmosphere to the earth loses a great deal of its energy, the loss depending on the position of the sun in the sky, the density of the air strata traversed and the amount of moisture and foreign matter in the air. The chemical rays show the greatest, the heat rays the smallest loss. The light intensity in the higher altitudes is much greater than in the lowlands, and this difference is particularly marked in winter. According to Dorno and Weber, Davos (altitude 5,000 feet) at noon in winter has four times the amount of light that Kiel (sea-level) has, while this difference is only half so great in summer. In about the same manner the volume of the ultraviolet rays increases with the increase in altitude. The difference in the ultraviolet ray's intensity in higher altitude in summer and winter, however, is comparatively small, while in the lowlands it is great. The effect of

---

* Read by invitation before the Chicago Pediatric Society, May 26, 1913.

light on the body is not as yet fully understood, but we may say when the body is exposed to sunlight for a period of time there results: (1) increased pigmentation; (2) increased growth of hair; (3) increased metabolism; (4) increase in number of erythrocytes; (5) local hyperemia; (6) decrease in number of respirations; (7) increase in depth of individual respiratory act; (8) fall of blood-pressure, and (9) stimulation of nervous system.

Under the influence principally of the ultraviolet rays, pigmentation takes place on those parts of the body exposed. This is as a rule preceded by an erythema of varying intensity, according to the strength of the light. The pigmentation is characterized by an increase of the pigment granules in the epithelial cells, as well as in an increase in the number of chromatophoric cells, which are probably epithelial cells which have migrated into the connective tissue. This pigmentation by some is considered a protective process on the part of the body against the ultraviolet rays. Others hold that it transforms short-waved, chemical rays into long-waved rays, which have a deeper penetration. A combination of the two views is probably more nearly correct. It is very important in practice, as Rollier states that prognosis and rapidity of healing are as a rule proportionate to the degree of pigmentation. This pigment absorbs the violet rays, but not the red.

All rays of light penetrate the human body, the violet or chemical rays possessing this power to a less degree than the heat rays.

Lenkei says that only about a hundredth part of the light falling on the body penetrates it 0.5 cm., but some rays reach a depth of from 5 to 6 cm. That light penetrates the thickness of the hand is proved by the experiments of Oninus. When light penetrates the skin, practically all the chemical rays are absorbed by the blood. This is a striking fact and probably some day will help explain the good results of heliotherapy. When we consider that exposure to light causes a local hyperemia, the amount of energy absorbed by the blood must be enormous. Von Schlaffer has also shown that blood during exposures to light absorbs light energy, which, in the dark, it can again transfer to a photographic plate. Is it not possible, as he says, that it can also surrender this accumulated energy to the internal organs, and thereby influence their function and possibly pathologic processes? Rollier rarely sees acne or furunculosis on pigmented skins, and during an epidemic of German measles noticed that all the well-pigmented children were free from eruption and even in those wearing jackets the eruption only appeared on those parts of the body not exposed to the sun-bath.

### TECHNIC OF HELIOTHERAPY AS USED BY DR. ROLLIER

While the French surgeons and even Bernhard of Samaden at first relied principally on local exposures of the parts affected, Rollier considers a general exposure of the body as fundamental and the local exposures as only secondary in importance. The dry, invigorating air of the higher altitudes is also called to assist the solar energy. This it does by increasing the action of the skin, thus aiding elimination, drying up wounds when present and increasing the general tone of the body. The treatment then is really a combination of light and fresh air. When light is not available the air-bath is used alone. According to Saake, mountain air also contains many more radio-active emanations than the air in the lowlands. Furthermore, in higher altitudes the differences in temperature in the shade and in the sun are very great, so that at Leyson when there is snow on the ground, temperatures of 95 to 120 F. in the sun are not uncommon. This allows the treatment to be carried on without interruption in winter, as the patients do not suffer from the cold.

Rollier in his address before the Gesellschaft deutscher Naturforscher and Aerzte in Münster in 1912 says:

> It is in surgical tuberculosis that we have seen the best results from heliotherapy, and we have made the treatment of it our life work. As a result of my experience in the use of the light-cure in higher altitudes, based on an experience of nine years, I maintain to-day that the cure of surgical tuberculosis in all its forms, in all stages, as well as at every age of life, can be accomplished.
>
> The closed surgical tuberculosis always heals, if one will only be patient, and above all if one understands how to keep it closed. To transform a closed tuberculosis into an open one means to increase the gravity of the case a hundredfold. A diminution of the vitality of the tissues is the inevitable consequence. . . . To regard a surgical tuberculosis as a local disease which can be cured by local treatment alone is a ruinous error. On the contrary, it is a general affection which requires general treatment. Of all infectious diseases it is the one in which the individual resistance plays a deciding part. Our first effort therefore is directed to improve general conditions and thus to bring about a healing of the local focus by treatment of the entire system. A rational local treatment is necessary as well, provided it is not too one-sided.

Patients on arriving at the sanatorium are put to bed for a few days, even those whose local condition does not make this imperative. They are thus allowed to become acclimated to the altitude. After three or five days as a rule, they are pushed out onto the verandas into the sunshine. The head is covered with a white hat or an umbrella, the eyes protected with dark glasses and a white garment worn over the body. On the first day the feet are exposed three times a day for five minutes; on the second day three times ten minutes, and the legs to the knees three times five minutes; on the third day the exposures are increased five minutes three times daily; on the fourth day thighs are included; on the fifth day the arms; on the sixth day the back and on the seventh the abdomen and chest, so that at the end of the first week some parts of the body are exposed for one and one-half hours per day. The exposures are increased five minutes three times daily until the patient gets a full sun-bath for from three to five hours daily. This, as a rule, is the maximum, although some bear the treatment for seven hours. Individualization of course is necessary, and in some instances the scheme of exposures must be modified to suit the case. Pulse and temperature are closely watched and used as an indicator of the patient's tolerance.

By this progressive increase of the time of exposure he avoids an erythema solare, and gradually the body acquires the desired degree of pigmentation which seems to be so essential. The rapidity and degree of pigmentation are as a rule in direct proportion to the power of resistance of the patient. Blonds and especially red blonds who pigment less seem to offer a more unfavorable prognosis.

Nervous patients must be treated carefully as they often complain of headaches and nervous symptoms. These restless, excitable patients receive more air-baths and shorter exposures to the sun, while the fat phlegmatic patients generally bear the sun-baths well.

As the healing of surgical tuberculosis requires rest of the parts affected, all cases except those of the upper extremities and lymph-nodes must be treated in bed. We must immobilize the parts. It the case of the upper extremities this is done with splints and bandages, which are removed during the exposure period.

Cases of tuberculosis of the hip, spine, lower extremities and peritoneum require immobilization in bed until healed; that is, until long after all pain has ceased and roentgenoscopy shows that the focus is healed. This, however, requires months and often a year or more. It is in cases of long duration particularly that we observe the better effects of treatment carried on in high altitudes over those in lower altitudes, for the former patients owing to the invigorating action of the mountain air, retain a good appetite, and with a good diet often take on weight. Not only that, but an increased tonus of the tissues, especially in children, is frequently seen. At lower altitudes loss of appetite and the depressing action of the heat interfere with the systematic treatment.

Rollier has discarded the use of all non-removable appliances for immobilization as antagonistic to the principles of heliotherapy. By their use, no matter how skilfully made, the activity of the skin is greatly reduced; exposure to sun and air is impossible, metabolism decreases and atrophy results. These factors tend to prevent healing and if healing does take place, the functional result is, in many cases, a poor one. All appliances for immobilization are therefore removed daily during the period of exposure, except occasionally in the case of very refractory children with spondylitis. In these cases he cuts large fenestra into the jackets. In general he applies extension apparatus, splints, bandages and removable corsets of celluloid. In many cases of spondylitis, a corset or jacket made of heavy material, which is in turn fixed to the mattress, is employed. Ambulatory appliances usually made of celluloid, so that they can be removed and treatment continued at home, are used only after the tuberculosis is healed to protect the newly formed bone.

Medication is rarely resorted to; children, however, receive cod-liver oil.

Cold abcesses unless interfering mechanically are given ample time to become absorbed. This occurs in a fair percentage of cases. Under all circumstances the rupture of an abcess is to be prevented, as a mixed infection is practically unavoidable and makes the prognosis so much worse. If necessary, they are aspirated and injected with iodoform, 10 per cent., in oil or glycerin, to guard against mixed infection. This is done even daily if necessary; every means and effort are used to avoid spontaneous rupture. If the patient has or develops a sinus, it is covered, when not exposed to the sun, with an alcohol dressing to prevent infection as much as possible. Sinuses, no matter where located, when exposed to light, first show an increased secretion, then gradually dry up, the granulations become healthy and complete healing is frequently seen. According to Bernhard, the scars resulting are firmer, yet more elastic, than when heliotherapy is not employed, and consequently produce less contraction.

The high fever due to mixed infection drops, large open wounds and ulcerations heal with a minimum of deformity, and thickening of joint capsules and exudates are likewise absorbed in many cases.

Franzoni, an assistant of Rollier, has recently published an interesting article on the behavior of bone sequestra under the influence of light. As a rule from three to five months are required for a sequestrum to form and free itself from the surrounding tissues. Heliotherapy increases the speed of evolution of the sequestrum and causes its spontaneous expulsion. Rapid and firm healing follows. By this method, only the necessary portion of bone is eliminated, and no new wound surfaces are created, as in the case of sequestrotomy. Franzoni has observed that when cloudy days intervene a sequestrum near the surface has retracted deeper into the cavity, to be fully expelled after further exposure to the sun.

The analgesic effect of the sun's rays is seen in almost all cases. In rare cases the symptoms become exacerbated but soon abate, and all cases show a marked lessening and more frequently an absence of pain after a short period of treatment. This, in turn, helps the patient by allowing him plenty of rest and sleep, the exposure to the sun being conducive to sleep itself.

In many cases of joint tuberculosis he finds a far better functional result after the use of heliotherapy than experience with other methods would lead one to expect. This he considers as characteristic of the use of the sun and air treatment! Passive and active movements are not employed.

Bardenheuer, assistant to Rollier, in a study of the blood, gives the following data:

During from the first to the third day of treatment, the red corpuscles usually increase about 500,000, and the white 3,000, the maximum in increase being reached about the third day. The leukocyte count in closed cases runs about 10,000, in cases with mixed infection from 13,000 to 17,000. He has found that cases in which the maximum increase in erythrocytes requires much more than three days are those offering a poorer prognosis. When healing starts there is a slight decrease in the number of erythrocytes.

The application of the treatments to specific seats of the disease is in substance as follows:

### TREATMENT IN VARIOUS FORMS OF TUBERCULOSIS

*Spondylitis.*—These patients are put to bed and immobilized as mentioned before. Children, if they wear a jacket, have a large fenestrum cut anteriorly, as the vertebrae in children are not much further removed from the surface of the abdomen than from the back. A gibbus, if present, is padded with cotton or a pillow, or, more frequently, the patient is placed on the abdomen with a triangular pillow under the chest. This position increases lordosis, and prevents, or when present, decreases the gibbus. After healing is verified by roentgenoscopy, a celluloid corset is worn. These cases require from one to two years.

*Coxitis.*—An extension is applied in bed and the pelvis is elevated on a pillow, to expose the entire coxofemoral trochanteric region to the sun. At the same time this avoids contractures. Abscesses when not absorbed are aspirated. The treatment requires at least a year, but splendid functional results are obtained.

*Lymph-Nodes.*—Bronchial lymph-nodes, lymph-nodes of the neck, have yielded beautifully to this treatment. In some cases the lymph-nodes appear spontaneously. In others it becomes necessary to aspirate; but even when there are sinuses the end-results are good, and the scars as a rule less disfiguring than in operative cases, complicated by infection. The treatment is contiued from six months to two years.

*Tuberculosis of Peritoneum and Ileocecal Tuberculosis.*—Even in these cases, the prognosis as a rule is good. Under the influence of the sun and fresh air, the pain soon subsides, exudates in the abdomen become absorbed; large tumor masses in the ileocecal regions, which were declared inoperable by Roux, disappeared and healing took place.

*Genito-Urinary Tuberculosis.*—The principal effects of heliotherapy in these sad cases is the lessening of pain and the amelioration of distressing bladder symptoms.

Tuberculosis of the bones of the hands and feet offers an especially good prognosis.

Closed tuberculosis of the pelvic bones is amenable to this treatment, but a mixed infection in cases of sacroiliac tuberculosis makes the case practically a hopeless one.

Patients with a combined local tuberculosis and tuberculosis of the lungs often show a marked improvement of the condition of the lung. As Rollier, by his method, exposes the thorax last, he has seen no ill effects such as hemoptysis. He says that bad effects such as congestion of the head, nausea, apoplexy, etc., are seen only when the method is improperly used and we fail to individualize.

Rollier's results[1] have attracted attention the world over, and such men as Bardenheuer, von Eiselsberg, Escherich, Kocher and others have written enthusiastically about the work at Leysin. Bardenheuer, who had very radical views on the treatment of surgical tuberculosis, now rarely resorts to a resection. He says, "Resection of a joint is a mutilating operation compared to Rollier's results."

In endeavoring to explain the action of the sun and the air, we encounter difficult problems. Several theories have been advanced. I shall not repeat them, as they are not convincing. We must here again accept the clinical results and content ourselves with empiricism. The pigmentation of the skin, the energy imparted to the blood by the absorption of rays, and the hyperemia of the skin probably all play an important part.

Good results are also seen in cases treated in the lower altitudes, although it often becomes necessary to interrupt the treatment on account of extreme heat or cold. Bardenheuer has reported on thirty-five cases treated at Cologne and is well satisfied with his results. He found that old fistulas, postoperative fistulas and old resections with mixed infections ofter healed promptly after exposure. Furthermore he employed the treatment in cases with multiple lesions which from a surgical point of view offered little hope, and saw complete healing take place, so that to-day he is one of the most ardent advocates of the Rollier treatment.

The principal drawback to the Rollier method or any other method of heliotherapy is, and always will be, the length of time necessary to obtain results, painstaking systematic work extending over months and years being necessary.

We must not lose sight of the fact, however, that when the ordinary orthopedic treatment is carried out a great deal of time is required likewise, and frequently at the end a resection endangering life becomes necessary. Not until sanatoriums are provided and especially places where the poorer class may find aid will heliotherapy be a complete success.

In the United States we have an abundance of places which would fill every requirement. Climate, plenty of sunshine and altitude can be had in Colorado, Arizona, California, New Mexico and in many other states; but in addition to this is required financial aid for institutions and the patients. The action of the states would be important. So much has been said in recent years on the subject of conservation that the matter of conservation of human beings and restoring them to usefulness cannot be foreign to American thought and American economic policies. The expense of bringing those afflicted with surgical tuberculosis back to health would be less than the burden imposed on state and charities in caring for the lifelong cripples created by this disease.

Here in the establishment of sanatoriums along the lines indicated is a field for the action of the state or for a broad charity.

Then, too, we could follow the good advice of Rogers, who says, "The study of solar phenomena and their relation to health and disease should be pursued with interest, and solar energy turned to account in maintaining the one and combating the other."

In the preparation of this article free use has been made of the publications of Rollier, Witmer, Bardenheuer, Jesionek and Franzoni.

# TREATMENT OF LOOSE TEETH DUE TO INFLAMMATORY DEGENERATION OF THE GUMS AND ALVEOLAR PROCESS *

JOSEPH HEAD, M.D., D.D.S.
PHILADELPHIA

The disease of pyorrhea alveolaris, in spite of its name, is not always associated with a flow of pus from the infected tooth-sockets. As a matter of fact, pus does not appear in 25 per cent. of the cases. The main symptoms are inflammation of the peridental membrane, bleeding of the gums at the slightest touch and a tendency for the teeth to elongate and be sensitive to mastication. Finally, the gums separate from the roots of the teeth, forming pockets in which salivary calculus and infection cause such centers of irritation and disintegration that the destruction of the teeth involved is only a question of time unless the tartar is removed from the roots, the mass of infection destroyed and the gums stimulated to reattach themselves to the roots of the teeth.

A single blind fistula from an infected root may cause the most profound nervous depression, which, being chronic, will be recognized only by its disappearance with the cure of fistula.

Osler, Goadby, Daland, Hunter and Billings, I believe, have not overstated the bodily ailments that time will show to be directly traced to mouth infections. That mouth infection is, in a great majority of cases, associated with Bright's disease, diabetes, cardiac, hepatic, renal and stomach disorders has been noted for a long time, but within recent years it has been shown that these disorders are, in many instances, ameliorated and, at times, entirely eradicated by the removal of the infecting foci from the mouth. My experience in the treatment of pyorrhea alveolaris with its associated tooth infections accords with these findings.

[1] Rollier (Verhan l. d. Gesellsch. f. Kinderheilk. d. 84 Versamml. d. Gesellsch. d utsch. Naturforsch. u. Aerzte in Münster) publishes a report of 6 0 cases in which 355 patients were adults and 295 children. Ther were 450 cases of closed surgical tuberculosis and 200 cases of open surgical tuberculosis. In the cases of closed surgical tubercu sis 393 patients were cured, 41 improved, 11 remained stationary, nd 5 died. Of the patients with open surgical tuberculosis, 137 were cured, 29 improved, 14 remained

* Read in the Section on Stomatology of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

* Because of lack of space, this article is abbreviated in The Journal. The complete article appears in the Transactions of the Section and in the author's reprints.

The development of medical science has now placed on the dentist not only primarily the repair and restoration of the teeth that they may look well and give efficient power of mastication, but the responsibility of deciding whether or not patients shall be inflicted with a long list of diseases that owe their origin and existence to infections within the teeth and the adjacent tissues. This question of autotoxemia has been a great shock to the prejudice of the medical world at large, but to the dental world, trained more along purely mechanical lines, with little or no bacterial knowledge, the question of autotoxemia is no less than revolutionary. It is as though cabin-boys had suddenly awakened to find that they had been steering the ships of the human fleet, without charts or knowledge of navigation, over rocks, whirlpools and mines, all the time blaming unavoidable fate for the death and disaster, when the wrecks, deaths and disasters were directly caused by their own well-meaning, blundering hands. The medical world at large cannot escape this indictment, but Dentistry, inasmuch as she recommends appliances and fixtures that cannot be cleansed, that obviously may cause and perpetuate toxemia, is overwhelmed by the contemplation of the long lists of preventable diseases and the gruesome toll of deaths that her well-meant efforts may have unwittingly occasioned. The manifestly undisputed fact that the removal of non-cleansable crowns and bridges have caused the rapid disappearance of heart murmurs, violent nervous derangements, duodenal ulcer, anemia, etc., is a convincing proof of what wholesale disease had been caused by the mechanical appliances now generally recommended.

When we come to pyorrhea and pyorrhea pockets, which the great majority of dentists class as incurable, we have come to the great divide, for those dentists who shall control and cure this great scourge shall take their places in the dentistry of the future, and those who neglect this important source of human disease shall be relegated to the spheres of those who unwisely attempted that which they were unfitted to accomplish; for the cure of pyorrhea alveolaris has been more or less successfully accomplished for the last fifteen or twenty years.

While, as previously stated, pyorrhea is associated with various disturbances of which it may be the primal and continuing cause, such as gout, Bright's disease, diabetes and cardiac, hepatic and renal disorders, such specific disease as syphilis, gonorrhea and tuberculosis, by their debilitating effect on the tissues of the mouth, may so lower the vitality of the gums that infections that otherwise would be repudiated, penetrate the peridental membrane and by a subtle toxemia still further depress the general vital forces. This infection having penetrated the gums, forms a small abscess that partly strips away the peridental membrane from the tooth-neck, forming a pocket, which once formed continues the disease even after the general systemic disorder may have been conquered. It is probable that some one of the numerous passing diseases, such as typhoid, measles, grip, or even a bad cold, has temporarily lowered the physical resistance of the gum tissue to the point of permitting the ever-present infection to penetrate and form the self-perpetuating pockets, thus leaving the pyorrhea to continue without apparent systemic cause.

If the systemic cause has passed and the pyorrhea has not created a new one, the disease may perhaps be successfully treated by local means and a permanent cure hoped for; but if the pyorrhea is associated with serious general disorder, local treatment, important as it is, can be held only as a palliative and must be supplemented by judicious systemic treatment. The most important systemic treatment in the cure of pyorrhea consists in the discriminating use of vaccines that will produce antibodies in the blood as supplementary adjuncts to the proper local treatment; and yet, important and valuable as the vaccine treatment unquestionably is, without the proper local treatment that removes infecting foci and stimulates the gums to heal and reattach themselves to the roots, vaccine treatment can only reduce the severity of the symptoms; it cannot effect a cure.

About seven years ago it was my good fortune to discover that commercial hydrofluoric acid would disintegrate tartar with no macroscopic action on either cementum or enamel of an extracted tooth. The poisonous action of this acid precluded its use as a therapeutic agent to be applied to the gums. Through an extensive series of experimentation it was proved that a 23 per cent. solution of ammonium bifluorid (an acid salt of hydrofluoric acid) will disintegrate the tartar on a tooth as readily as hydrofluoric acid itself and also leave the tooth apparently unsoftened. The following is a safe, practical method for its manufacture: Forty c.c. of commercial hydrofluoric acid should be placed in a wax bottle and 27 gm. of chemically pure ammonium carbonate slowly added, a small lump at a time, the bottle being closed after each addition to prevent undue escape of fumes. When this mixture is allowed to rest for twenty-four hours it is ready for use. The temperature of the mixture during manufacture should not exceed 60 degrees Fahrenheit. The solution of ammonium bifluorid thus obtained gives excellent therapeutic results. Any variation in the strength of the acid made by this method seems to be of no importance chemically.

The solution of ammonium bifluorid may be injected once or twice a week into pockets around loose teeth, but care must be taken not to inject it into fresh cuts, as such procedure will cause great pain. The patient should spit without rinsing the mouth with water, the saliva acting as a protection against irritation. After one or two injections the soreness and inflammation will largely disappear, and even the general symptoms of toxemia will sometimes be found to have abated. The tartar scale that could not be easily and painlessly removed at the first two treatments will now tend to be so loosened that its thorough removal by scalers will be easy for both patient and dentist. After four or five applications, one week apart, black scales that have escaped the instruments will sometimes be found floating loose in the pockets, so that they can readily be picked out; finally, the root will become as smooth as velvet to the touch of an instrument. When this stage has been reached it will be found that the scalers cannot be so deeply carried into the pyorrhea pockets as was easily possible in the beginning. To do so causes pain and a free flow of blood. This indicates that new granulations are forming, which should not be ruthlessly broken up either by instrumentation or by injection of the bifluorid into them. Once each week the solution should be allowed to flow gently into the pockets, a procedure which results in continuous healing and is not productive of pain. Careful exploration for tartar on the root within the pocket is always advisable. Reattachment of the gum to the root, however, can be accepted as assurance that that portion of the root has been thoroughly cleansed. The scaling in that place should then be discontinued, while the weekly applications of the bifluorid alone should be used. If, however, at the end of two or three months any of the pockets have not entirely healed they should be re-explored with scalers and the treatment repeated as for a new case, although by this time most of the original pockets will have disappeared, and where they existed the gums, with a slight contraction at the neck, will be found firmly adherent to the tooth. Teeth that have lost more than half of their gum attachment have become, under this treatment, firm and comfortable to the action of normal mastication.

Let us now consider some of the other means of local treatment in the cure of pyorrhea alveolaris. Loose teeth may be splinted together so as to give immobility, but this should always be done in such a manner as not to prevent thorough cleansing of the gum around their necks. Any malocclusion should be remedied so that loose teeth may be relieved of the excessive pressure of mastication due to thickening of the inflamed peridental membrane. When a pocket has approached an apical foramen near enough to infect the pulp, the pulp should be destroyed and the root canals thoroughly sterilized and filled. This should be especially looked to in the case of molars in which the pocket extends through the bifurcation and down to the tip of one of the roots. It is sometimes excellent practice to cut the crown midway through the grinding surface through the juncture of the roots, finally extracting the diseased root with its side to the crown. This exposes the other root or roots so that they can be filled and cleansed as easily as a bicuspid. With upper molars, if the palatal root is necrosed, this operation is most satisfactory as it leaves the mouth to all appearances unchanged, and works for greater stability and more rapid recovery by not forcing the remaining root or roots to stand more than their fair share of mastication.

An excellent mouth-wash for use at home consists of a saturated aqueous solution of sodium silicofluorid which amounts to a 0.61 per cent. solution. This, when held for a minute in the mouth, morning and evening, and freely swashed for at least a minute through the teeth is a great assistance in relieving inflammation of the gums. Like the bifluorid it seems to restrain the deposition of tartar on the teeth, except in about 1 per cent. of cases, in which it seems to increase it slightly. But even in these cases the gums heal promptly and the superficial deposit is easily removed from the teeth with brush and pumice. The disagreeable flavor of the solution can be disguised by adding an equal amount of sodium chlorid or a judicious quantity of aromatics.

An efficient tooth-powder that will liberate enough free oxygen to make from 40 to 50 drops of a 3 per cent. peroxid solution for every 10 grains used on the brush in the mouth is as follows:

| | |
|---|---|
| Magnesium peroxid (200 mesh sieve) | 60 parts |
| Sodium perborate | 30 parts |
| Castile soap and flavoring | 10 parts |

This can be used morning and evening for brushing the teeth and should be swashed around the interstices for a full minute before being ejected from the mouth. Without thorough cleansing and brushing of teeth and gums morning and evening antiseptic washes will, however, be of no avail. Since the tooth-brush cannot cleanse between the teeth these surfaces should be swept free from bacterial deposits with floss-silk morning and evening, and the teeth and gums thoroughly brushed with strokes not less than an inch and a half long, and rotary wherever possible. The brush should be small, not over an inch and a half long, the bristles not over a quarter of an inch, and narrow, so that when the mouth is partly opened the brush can be placed between the ramus of the jaw and the third molars. Most brushing does not extend beyond the spring of the bristles, which instead of giving bristle friction merely pivots the bristles without cleansing. The upper and lower third molars more frequently decay and are subject to pyorrhea alveolaris simply because they are not cleansed. Structurally, they are not weaker than any other teeth. At each visit of a patient it is most essential that the necks of all the teeth be examined for bacterial plaques that may have been accumulating undisturbed since the last visit. The patient should be shown what movements of the brush are necessary for their removal, for a final test of a method of brushing the teeth and gums is, Does it clean away the bacterial plaques? Ninety-nine out of a hundred cleanly people never brush the thick bacterial plaques from their third molars, or, as a matter of fact, from half the other teeth, simply because they have never been taught how. Gums as well as teeth should be thoroughly brushed twice a day of all bacterial plaques. Observation on my patients proves that healthy gums are no more injured by vigorous brushing than is the skin adjacent to the finger-nails. Inflamed soft gums will unquestionably be made sore for the first week or two, but persistence on the part of the patient and assistance on the part of the dentist in touching up the sore spots with silver nitrate will soon strengthen the gums to almost any friction the tooth-brush can give them. The question of vigorous cleansing and massaging the gums with the brush is not only a question of removing external films of infection, but is also for the purpose of producing an auto-inoculation that will create antibodies in the blood for the purpose of combating the disease, a vigorous massage of the parts causing a local hyperemia, which enables the antibodies in the blood to come into more intimate contact with the infecting bacteria. This is a most important phase in the cure of pyorrhea and one that has not been sufficiently emphasized. The formation of antibodies for the cure of pyorrhea is a means of eradicating pyorrhea from the system. The auto-inoculation caused by vigorous gum brushing combined with the judicious use of carefully prepared vaccines have given results of a systemic improvement that are little less than marvelous.

Medical literature is so full of the reports on successful vaccine treatment for mouth infection that they cannot but convince the most skeptical that there must be value in the treatment. Goadby's work in this field is deserving of great credit Cummins[2] has published a recent article on this subject wherein Goadby's methods are followed. The work of Leary and his associates is more in accordance with modern bacteriologic methods, however, and their reports are more in accord with the bacterial findings of this paper.

About two years ago I began the vaccine treatment as an adjunct to my local pyorrhea treatment. I was decidedly skeptical because pyorrhea does not seem to be caused by a specific bacterium, but may be caused by any one of several species, or various combinations of these. Nevertheless, from the very start such increased improvement locally and systemically was obtained that the great value of the treatment could not be doubted. The results in almost every case showed a consistent healing of the pockets and a disappearance of infection from the gums. In about 50 per cent. of the cases there was a distinct improvement in the general physical condition, which, as before stated, being chronic was sometimes made more apparent by its absence than its presence. In the forty cases that are used as the basis of this report, the streptococcus, staphylococcus, *Bacillus influenzae*, pneumococcus, *Micrococcus catarrhalis*, diphtheroids, Friedländer bacillus and an occasional unidentified bacterium were used in the vaccines. The *Streptococcus viridans* appeared in about 25 per cent. of the cases. That the vaccines for pyorrhea alveolaris for forty cases contained such a consistent combination of similar germs for so many cases with so comparatively few unidentified strains may be partly due to the method used in collecting the specimens so as to exclude the incidental or extraneous flora of the mouth. My method will now be described.

---

[2] Cummins, R. C.: Jour. Vaccine Therap., March, 1913, p. 59.

When the infected area appeared at the tip of a root in which the pulp had died and the root canal had been filled, the culture was always taken through the root canal, which was drilled out with a fine sterilized piano-wire drill until the end was nearly reached. The canal was then sterilized with phenol (carbolic acid), wiped dry with cotton and then blown out with hot air. When this had been accomplished and the tooth had been carefully guarded with a napkin to prevent infection from the mouth, another sterilized drill was passed down to the end and then plunged through the tip into the infected area. This was then streaked over the blood-agar in the ordinary manner. At times, however, the infected area appeared near the tip of a root or roots in which the pulps were alive. In this case the root-canal method of obtaining the specimen was not feasible, so the following method was substituted: The mucous membrane over the indurated infected spot was cocainized and a thin cautery plunged down to the bone. A sterilized bone-drill was then passed through the outer plate of the alveolar process and the patient dismissed for two days. On his return the opening in the gum, on being protected with a napkin, was cauterized with pure phenol and then wiped dry. Then the sterilized point of a small sterilized platinum-pointed glass syringe or platinum spear was inserted into the bony opening made previously by the drill, and a small drop of bloody fluid extracted, which with due care was transferred to the blood-agar medium. This material was supposed to contain the bacteria that had gathered for the purpose of preventing reorganization of the tissues.

To take a specimen from a pyorrhea pocket the following method was used: The neck of the tooth was first carefully washed with 95 per cent. alcohol so as to remove all outside bacteria as much as possible. The tooth was protected from mouth infection by a napkin, and then a small cup-shaped spear of thin platinum was heated to a cherry red and plunged to the bottom of the pocket. Such a procedure it was thought would get not only the pus but also a slight amount of blood from the walls of the cavity. It was thought that the hot platinum would kill any extraneous flora, while the cooled metal would carry to the blood-agar only the germs directly responsible for the disease in question. It must not be forgotten that pus is sometimes sterile, while the true cause of infection may lurk within the walls of the abscess from which the material is being obtained.

The vaccines were then made up so as to contain all the germs found, except the spore formers and the anaerobes that were not grown. While the bacteria of these classes may sometimes play a rôle in the infection the results of vaccine treatment indicate that in these cases their rôle is a minor one. The staphylococci were made to give 300 million to the cubic centimeter. Streptococci, diphtheroids, pneumococci, *Micrococcus catarrhalis, Bacillus influenzae* and unclassified bacteria were put in so that each would show 50 million to the cubic centimeter. In ordinary cases of chronic pyorrhea the initial dose is 75 million staphylococci and 12 million of each of the other bacteria, and the dose is steadily raised according to the reaction at the site of inoculation and the general systemic response. If the patient showed exceptional frailness or the inflammation was exceptionally acute, the initial dose was reduced to 37 million staphylococci and 6 million of each of the other bacteria. These doses were generally given a week apart in the arm, or, in thin patients, in the back.

I have not used the opsonic index in the treatment of pyorrhea alveolaris. I feel that clinical symptoms have been a sufficient guide. An interesting observation which I have not seen mentioned elsewhere is the occasional persistence of the induration which forms at the point of injection. It has appeared to me that this can be due only to a lack of digestion and absorption of the bacterial bodies. So long as the induration markedly persists we have an indication that the potentialities of the vaccine injection have not been exhausted. Therefore, further injections may be temporarily withheld or smaller doses given while absorption in the seats of induration is stimulated by massage. This method gives excellent results, and tends to minimize the danger pointed out by Allen,[3] when excessive reaction is caused by doses which may have been perfectly well borne on several previous occasions. As Allen says, however, it should always be borne in mind that, if the systemic reaction lasts over twenty-four hours, it is wise to increase the interval between the doses, and a larger dose should not be given especially if the patient makes good progress on the smaller dose.

If there is a tendency to the rapid formation of creamy tartar deposits on the teeth prior to vaccine treatment, it will be noted that, as the antibodies are formed and the gums show signs of healing, the tartar will be deposited much less rapidly and that the tartar deposited is of a more solid, removable nature and does not tend to burrow under the gum margins. This change in the deposition of tartar I have finally come to regard as a distinct symptom of the successful progress of the vaccine inoculations.

When a pyorrhea pocket shows sudden signs of inflammation during treatment it is always wise to open it surgically with a drill along the root to be sure that there is no back-pressure of pus, and that the antibodies have full opportunity to enter the seat of infection for the purpose of aiding in the cure; for above all things it should be remembered that the vaccine treatment can be successful only when accompanied by judicious local treatment of a surgical and therapeutic character. This applies to all foci of infection whether in the gums or in the impaction of a bowel or anywhere else in the system. It is imperative, therefore, that there should be sympathetic cooperation with the family physician, whose intimate knowledge of the patient and whose careful diagnosis of foci of infection other than those found in the mouth will greatly increase the percentage of successes and add to the permanence of the cures.

---

[3] Allen: Vaccine Therapy and Opsonic Index, Blakiston, Philadelphia, 1913, p. 112.

Allen[3] speaks of the value of citric acid in 30-grain doses three times a day for the purpose of softening the lymph-wall around the foci of infection by reducing the agglutinative power of the blood. I have found this treatment of service, but give it in the form of an ounce of lemon juice three times a day, which is the equivalent of about 34 grains of citric acid.

I shall now report a few detailed cases.

Cases 1 and 2.—A young man with pronounced pyorrhea and several fistulas in the gums came to me so despondent that he thought he was going to die. Local treatment caused improvement, but two of the fistulas would not heal. An autogenous vaccine was made in March, 1912, from material obtained from the worst fistula. It contained only a single strain of streptococcus. After four injections, a week apart, the patient gained in weight and then started slowly to lose weight, but as he felt better and the gums improved, the treatment was continued until June, when there was a great improvement in the gums and both fistulas had healed. In the fall the patient returned and, as he and his family physician said that the vaccine had done him so much good, I made another vaccine from a small pyorrhea pocket and obtained four strains of streptococci and a *Staphylococcus aureus*. This treatment caused a complete healing of the mouth so that it was apparently absolutely healthy; the patient's skin cleared, he gained weight and felt, as he said, well. The mixed vaccine seemed most effective.

He begged me to give the vaccine treatment to his wife, who also was suffering from pyorrhea. She had almost the same experience, except that she did not gain weight (her weight was normal), but her mouth showed great improvement and she slept better and felt a great lessening of nerve tension.

Case 3.—A young woman was vaccinated with a Gram-negative bacillus, 50 million to the cubic centimeter, with some improvement, but not marked. Later a second vaccine was made of *Staphylococcus aureus* and *S. albus*. The gums showed marked improvement, but the soreness around two or three teeth still persisted; the skin generally, from being itchy and showing a tendency to pimples, cleared up and to her great delight remained sightly and comfortable.

Case 4.—Mrs. A., aged about 50, came to me with all the teeth loose, complaining of great fatigue, trouble with the eyes, constipation and a steady loss of weight. In six months the vaccine treatment had markedly tightened the teeth and her chronic fatigue and constipation were gone; the wrinkles vanished from her skin owing to an increase of weight from 115 to 127. Her eyes, she says, were so improved that she could readily read what before was impossible or accomplished with difficulty.

Case 5.—A married woman, aged 40, who had been under my local treatment for about two years took a vaccine last fall composed of a streptococcus. She had a complexion covered with red patches, gout in the right eye, hemoglobin 67 and great depression with constant fatigue. In six months the hemoglobin went up to 93, the gout disappeared from the eye, her complexion cleared and the gums made more progress than had previously been made in two years under local treatment. Her greatest satisfaction lay in the fact that she slept well, which prior to the vaccine had not been the case.

In three cases as the gums and abscesses healed marked redness of the nose disappeared. This was associated with great clearing of the complexion and a gain in weight. In other cases there was a consistent healing of the gums that seemed much more rapid than that usually obtained from local treatment alone, but with many of them the time is too short to be sure of a permanence in cure.

In one case that refused to yield either to local or

Such a depressing focus was obviously a sufficient reason for the poor results obtained, and as the patient refuses to have an operation the prognosis is not good.

Vaccine treatment judiciously used seems to be so valuable in the cases of pyorrhea that it should, in my opinion, always be given a fair trial and always in sympathetic cooperation with the family physician.

1500 Locust Street.

### ABSTRACT OF DISCUSSION

**Dr. Thomas B. Hartzell**, Minneapolis, Minn.: We sometimes cause deeper infection and greater disturbance, if treatment of the mouth is undertaken immediately prior to operation in other parts of the body. I am convinced that I have been responsible for bringing about two or three cases of pneumonia by disturbing areas of granulation tissue around teeth that needed care. Dr. Mayo, in a recent conversation, confirmed the idea that operative interference in mouths to clear them of bacteria immediately preceding great surgical operations, is an unsafe procedure. Treatment of the mouth should be accomplished by satisfactory measures two or three weeks before any extensive surgical operation is undertaken.

I believe that the bacterial vaccines should be used in conjunction with other measures, and that if used properly they have a vast field of usefulness.

**Dr. Thomas L. Gilmer**, Chicago: Referring to the benefit derived from antiseptic mouth-washes, I suspect that the mechanical cleansing of the teeth rather than the destruction of the bacteria by the medicament caused the improvement indicated. Bacteria are not destroyed by any germicide that I know of which is not also injurious to the mucosa of the mouth. Dr. Black recommends the use of a bulb-syringe with a moderately small nozzle for cleansing the interproximal spaces, especially when the gum septum is much destroyed by pyorrhea or otherwise. If considerable force is applied to the bulb, food and other debris is dislodged. This should be used only as an adjunct to the brush, silk floss and toothpick.

**Dr. C. H. Oakman**, Detroit: I am glad to know that those who spoke of vaccines do not hold to the use of vaccines alone, but believe in instrumentation. Dr. Head spoke about the use of peroxid of hydrogen. Three per cent. peroxid of hydrogen should not be condemned, but, as a rule, peroxid of hydrogen used in the mouth in stronger solution would be contra-indicated unless combined with lime-water or some other alkaline agent. I saw two patients in the hospital who were suffering from so-called rheumatism which involved principally the joints of the hands, wrists and elbows. Both had pyorrhea alveolaris combined with alveolar abscesses. One patient had been an invalid for several years. They were given pyorrhea treatment, which eliminated considerable of the infectious material; first stock vaccines and then autogenous vaccines were used with most excellent results. Within two weeks these patients showed marked improvement with regard to the mobility of the joints.

**Dr. L. Duncan Bulkley**, New York: I find the use of peroxid of hydrogen as a local remedy very satisfactory. I use it, first, in ordinary strength, increasing it, as necessary, even to full strength. I insist on slow and complete mastication, with some self-massage, as a means of promoting nutrition in the gums, and I am positive that all the cases in which this has been well carried out have been benefited, and the trouble has often been overcome. I never could see the sense in simply trying to relieve the trouble locally by cleaning out or disinfecting the socket of the tooth.

It is remarkable that the three or four places in the body that have the most micro-organisms—the scalp, the mouth, the scrotum and the vagina—are the places which yield best to surgical treatment. We all know how easily wounds in the mouth heal; wounds in the scalp are easiest to treat. There is something other than the simple action of organisms to be accounted for in pyorrhea, and we should always study the soil, or state of the system, on which they flourish; when this is in the best condition possible, a relatively small amount of local treatment acts efficiently.

Dr. Truman W. Brophy, Chicago: What has been said about infection would naturally make us extremely timid regarding operations in the mouth, if it were not for the facts that have been named by Dr. Bulkley. When one may operate in the mouth month after month without getting an infection, it impresses us with the feeling that, after all, these pathogenic micro-organisms are not so much to be dreaded as one would assume on general principles. We all know that we cannot remove them from the mouth by any kind of washing, irrigation or brushing; that they become imbedded in the mucosa in such a way often that their removal is absolutely impossible, and that even in the presence of pathogenic micro-organisms we do get good results without infection. We ought, however, to do everything in our power to make the parts as clean as possible. I think that it is wise, when possible, to irrigate the nose, mouth and pharynx prior to any operation in that field.

Dr. A. Parker Hitchens, Glenolden, Pa.: The discussion to-day indicates that we are at last getting away from the idea that bacterial vaccines alone can cure this infection. The reason we have local infections at all is because the bacteria have been assisted in some way to overcome the body's normal antibacterial forces. The assistance in pyorrhea comes through serumal calculi, tartar-plaques, foreign bodies and traumatism. The resulting inflammation apparently hinders the ready access of the normal curative substances in the blood and lymph to the organisms present. There is just about space enough between the cells constituting the inflammatory area for toxic substances to pass out into the tissues, but not sufficient room for antibacterial substances to get in; so that, even though the opsonic index is raised, no benefit results to the patient. The rational way, therefore, to treat an infection, the inception and continuance of which is facilitated by the presence of foreign irritating substances, is to remove the foreign bodies and possibly also the inflammatory tissue; in other words, local treatment must be resorted to.

Dr. Nelson T. Shields, New York: One point has been overlooked, and that is in regard to the saliva. After thorough prophylaxis and the removal of all the micro-organisms from the fermentation of food, you leave the mouth in a normal condition because the saliva counteracts all other acidity that forms when the saliva is normal. But for the saliva we would not have teeth very long.

A splint for holding loosening teeth should be so made that not only the saliva can circulate between the teeth just as well with the splint in place as without it, but also that the soft tissues will be protected. This is best done by extirpating the pulps from all teeth involved in the splint and, after thorough cleansing mechanically, asepsis being maintained, filling the canals with gold at their apices and with oxychlorid of zinc in the remaining portions. This being done the teeth can be prepared in such manner that the mechanism in the construction of the splint will allow the saliva to circulate between the teeth, which will keep the mouth normal. The extirpation of the pulps and canal-filling described will prevent the wasting of alveolar process and gums, which would certainly follow should this important point be overlooked.

---

**Feeble-Mindedness.**—The importance of this problem is recognized in an instant when we learn that at the very lowest estimate 25 per cent. of our criminals belong to this class. Perhaps 50 per cent. of our prostitutes are feeble-minded girls; the same is true of our paupers, our drunkards, our ne'er-do-wells; in fact, we now recognize that a large percentage of the various classes of people who make our social problems are mentally defective. Twenty-five per cent. is a minimum estimate, while it has been shown that in all probability 50 per cent. is much nearer the truth, and it may run even higher. A superintendent of one reformatory for men estimates that 75 per cent. of his inmates are feeble-minded; careful tests of the girls in a reform school have shown 72 per cent. feeble-minded. In fact, wherever there are any statistics, it invariably points to the higher figure.—H. H. Goddard, in *Illinois Med. Jour.*

# A CASE OF CONGENITAL MYOTONIA *

G. W. BOOT, M.D.
CHICAGO

Although the subject is outside my specialty, the rarity of the disease and the lack of knowledge concerning it justify me in reporting the following case:

*Family History.*—Patient's father is alive and well, active physically and mentally. The mother died of hemorrhage following some abdominal operation, at the age of 28. Father and mother were first cousins. Patient's father married again and none of the children by the second marriage are afflicted with the patient's disorder. The patient's paternal grandfather died at the age of 60 of spinal meningitis, and his paternal grandmother died aged about 35, from causes unknown to the patient. The maternal grandfather is alive and well, though slightly troubled with asthma, and the maternal grandmother died at the age of 55 from causes unknown to the patient. The patient's mother suffered from a disorder similar to his. This is shown by the disinclination she manifested toward going up and downstairs; the patient also finds this difficult and rather dangerous.

She had three children—all boys. The first died when about 8 years old and showed no signs of any similar trouble. The second child was 2 years older than this patient and manifested the same symptoms, having many falls as a child. He had an unusually active mind and studied hard in college subsequent to an attack of scarlatina. Following this he had a mental breakdown and was placed in a private sanitarium, where he died. The post-mortem examination which I made showed nothing externally beyond an unusually good muscular development and a few slight abrasions. At this time I knew nothing of his peculiar symptoms, so no muscle was removed for microscopic examination. When the skull was opened the calvarium was found thin and translucent in two places just outside the sagittal suture, about where it crosses the coronal suture. The dura was congested in those portions which corresponded to these areas, and was densely adherent to the deeper structures as well as the cortex. Except for this area of adhesion, the brain appeared normal. There was no fracture of the skull; the frontal sinuses and the temporal bones were normal. The lungs were found darker than usual. Over the upper lobe the right lung was adherent to the back of the chest, and the lower lobe adhered to the diaphragm, while the left lung was normal throughout. All the other thoracic and abdominal organs were found to be normal. Death had apparently occurred in a convulsion.

*Personal History.*—The patient, E. H., aged 21, is the youngest of the three children. His trouble began early in life. He remembers that at the age of 5 he had difficulty in arising from a sitting to an erect position, particularly if he had been sitting on the floor. His muscular trouble has caused him many falls. At the age of 12 he fell about 15 feet, struck on his head in the left temporal region, was unconscious for about twenty minutes, and after the fall could not see for about an hour. This was purely an accident and not the result of the myotonia. At the age of 14 he fell backward down the basement stairs, striking the back of his head on the cement floor, but was not injured. This fall was caused by loss of balance and inability to regain it on account of muscular spasm. At the age of 15 he fell forward on the same stairs. This time he fell like a log, toppling over with all his muscles rigid. He struck on his forehead and was unconscious for a short time, after which an abscess in the frontal region and many headaches developed. He has had chicken-pox, mumps and scarlatina, the latter at the age of 13.

*Present Condition.*—He has the typical state of myotonia, that is, when his muscles have rested and then are contracted, particularly if they are suddenly contracted, they are thrown into a tetanic condition, from which they do not relax promptly. If he rises from a chair after sitting for a short time his muscles contract and he cannot walk. Sometimes this condition of spasm will last for a minute or more. As a boy he could not take part in races or ordinary athletic games because he could not start quickly. When he got into fights he would always be thrashed before he could get into action. At one time he attended military school and found great difficulty in going through the prescribed tactics. After motion of the muscles is established he can move quite rapidly, but great resistance must be overcome before movement is secured. Going up and downstairs is perhaps the most difficult of all actions for the patient to perform, unless it is getting out of bed in the morning. After a night's rest he has much difficulty in rising. As his arms are less affected than his lower extremities, he first gains support on one elbow, then on the other, and so gradually gets control of muscle action. Cold weather has a marked influence for the worse on his condition. He tires more easily than ordinary persons, presumably because the spasm of the muscles causes more fatigue products to form, and in consequence he seems to require more sleep than the average individual. While the myotonia affects all the voluntary muscles to a greater or less degree, it is more marked in the lower extremities. It appears to be a true hypertrophy, for the muscles are firm and not soft or flabby. He must exercise extreme care when crossing busy streets, for if he were about to be run down by some vehicle he would be unable to move with sufficient speed to get out of the way. It is impossible for him to get on or off a street-car while it is in motion, partly because he cannot move quickly and still maintain his balance and partly because he cannot release the hand-rail promptly.

---

* Presented before the Chicago Neurological Society, Feb. 20, 1913.

*Examination.*—The myotonia appears in the ciliary muscle to a slight extent, for he apparently experiences some slight difficulty of accommodation in looking at objects which are at different distances. If he looks steadily at a near object and then suddenly at a distant object there is a temporary blurring of vision. There is apparently a slight tardiness in response in the muscles of the eyelids. The myotonia is very marked in the masseter muscles. If he bites forcibly these muscles do not relax at once, but there is a considerable interval before he can open his mouth wide. No difficulty could be demonstrated in the muscles of the tympanum. The heart sounds are normal except that they appear rather loud. Any sudden alarm has a marked influence on the pulse-rate, increasing it greatly. The pulse-tracings show that exercise produces an unusual increase in the upstroke of the sphygmogram. "Stretching" causes a marked increase in the pulse-rate, but the blood-pressure is normal. Speech is rather hesitating. Whether or not this is due to an effort to get the muscles of speech in action I have not determined. It seems to me rather to be of mental origin. The diaphragm participates in the spasm, for after a strong exhalation in coughing or sneezing he cannot at once inhale. At times this causes dizziness. He has never become unconscious from spasm of the respiratory muscles. The deep reflexes cannot be elicited. I could find no jaw-jerk, elbow-jerk, wrist-jerk, knee-jerk or ankle-jerk. Light stroking of the abdomen elicited no response. The cremasteric and plantar reflexes are present. His troubles do not increase with age. No electrical tests have been made.

This case brings up several important problems for this young man. What are the chances of his transmitting this disorder to posterity if he were to marry? The condition of the sexual organs appears to be normal. Another problem concerns the occupation he must follow. Ordinary labor is out of the question, as he tires too easily and he cannot move quickly. The upper extremities being less involved than the lower, it seems to me that some occupation would be most suitable in which the chief muscular demands were made on the upper extremities. Also as regards life insurance, and in particular accident insurance, such an applicant would be a poor risk. Whether the disorder will shorten his life, except by accident, is problematic. What of his mental condition? Is there any danger of his becoming insane? His brother's affliction in this respect seemed to be closely connected with the results of the trauma he suffered to his head.

Among the questions of scientific interest that arise are the following: Where is the seat of the lesion or malformation causing this trouble? Is it in the nervous system or in the muscles? What is the relationship of this disorder to pseudohypertrophic muscular paralysis? Is the myotonia in any way related to tetany? Has it any connection with deficiency or perverted action of the secretion of the ductless glands? Does his metabolism differ from that of the ordinary individual?

# ENTEROLITHS

## REVIEW OF LITERATURE WITH REPORT OF CASE

Frederic D. H. Coerr, M.D., New York
*Assistant Visiting Surgeon, Fordham Hospital*

A tentative diagnosis of enterolith has probably been made frequently, only to be disproved at the time of operation. Conversely, most of the enteroliths reported have been discovered in exploratory laparotomies or on the post-mortem table.

The rarity of the condition is no reason for not bearing it in mind when endeavoring to determine the nature of some obscure abdominal condition, with or without intestinal obstruction.

It is self-evident that no classical picture can be drawn, as the signs and symptoms vary with the size, character and origin of the enterolith and its location in the alimentary tract, which may be anywhere from the stomach to the rectum. The diagnosis, therefore, is one which must be made chiefly by elimination, with the assistance of the laboratory and the Roentgen ray.

A positive, preoperative diagnosis may not be essential in all cases, but in some it would have prevented a fatal outcome, and in others saved years of distress and invalidism.

To stimulate a possible interest in this condition and to place on record one of these surgical curiosities, I submit the following brief review with the report of a case which I treated.

We are all more or less familiar with the hair-balls found in the stomach and intestines of the herbivora and in animals which have the habit of licking their coats, as well as the coats of their fellows. These frequently attain considerable size, and are composed of hair and husks, matted together with hard fecal matter. These are true enteroliths of fecal origin, and although common in animals, are rarely found in man.

Oriental bezoars[1] formerly, and possibly now, of medicinal use in certain countries, are intestinal concretions which probably were formed in *Capra aegarus* and *Antilope dorias*. They are usually spherical or oval, of a dark olive-green color, due to biliverdin, with a smooth, shining exterior, and composed almost entirely of lithofellic acid.

False bezoars, which come from the Eastern countries, have a brownish-black color, and are composed chiefly of ellagic acid, probably derived from the tannin contained in the food consumed by the animals which yield them.

Many foreign substances find their way into the human intestinal tract, but it is rare for any of them to form a nucleus of a concretion of sufficient size to cause intestinal obstruction, unless per chance it lodges in a Meckel's diverticulum or in some pouch of the intestines, as in the case reported by D. M. Greig,[2] in which the obstruction was relieved by the spontaneous evacuation, through an umbilical fistula, of an enterolith 2½ inches in circumference and weighing 24 gm. This may have been a true enterolith, but more probably it was a phosphatized gall-stone; since, judging from all the cases reported, gall-stones are found to be the most frequent cause of intestinal calculi in man. They may remain in the intestine for years, causing no trouble until, gradually increasing in size by accretion or being reinforced by accumulation of other stones, they give rise to symptoms of obstruction, either partial or complete.

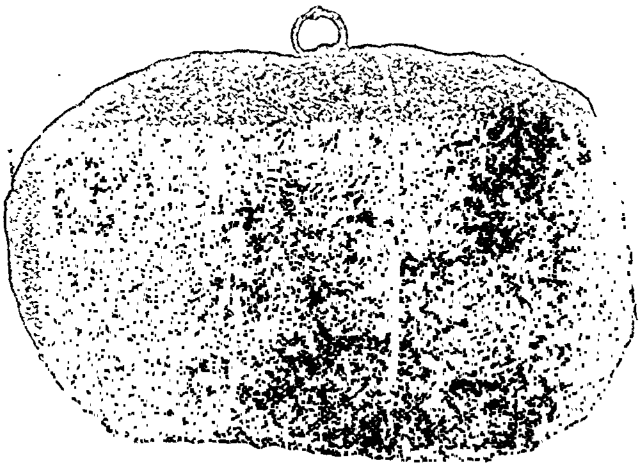
---

[1] Smith, E. E.: Reference Handbook of Medical Sciences, 1901, iii, 231.

[2] Greig, D. M.: Lancet, London, Dec. 3, 1910, p. 1613.

U. Gabbi[3] reports a case of this kind in a peasant, aged 45, who, one and one-half years after an attack of hepatic colic, was suddenly seized with a violent pain in the right inguinal region, followed by nausea and vomiting. The pain became rapidly more severe and generalized; the abdomen greatly distended, accompanied by tenesmus without evacuation. Temperature only slightly elevated and pulse accelerated. Purgatives and enema relieved the distention sufficiently to disclose in the region of the ileocecal valve a palpable, freely movable tumor with a hard nodular surface. Later, a hemorrhagic exudation occurred in the peritoneal and pleural cavities. This was removed by aspiration. Stools became normal, but urine contained much urobilin. Patient began to recover and left the hospital, but, according to his story, entire restoration to health came only after a chestnut-sized, whitish stone had been evacuated in a stool, followed by eight bean-sized stones and about fifty small stones.

According to Gabbi, the large number and small size of most of the evacuated stones exclude a diagnosis of enterolith of the feces. Since an attack of hepatic colic had previously occurred, it is probably that these gall-stones had remained in the intestines for a year and a half, and only after that period had given rise to the preceding symptoms. It is a fact that gall-stones, during a protracted stay in the intestines, become phosphatized and adopt the characteristics of true enteroliths. It is also a fact that gall-stones may more or less completely close the intestine and thus produce attacks of severe intestinal colics, especially if they lodge in large numbers in the narrow portion of the ileum, just above the ileocecal valve. Gabbi attributes the hemorrhagic quality of the exudate to previous malarial attacks.



Enterolith, measuring 15.4 by 12 by 10 cm. and weighing 945 gm.

J. H. Miller[4] reports a case of obstruction of the bowels by enterolith, composed of a phosphatized gall-stone. Recovery in this case also occurred after passing the stone by the rectum. The specimen weighed 183 gr. and measured 1¼ inches in length and 1 inch in width.

The case of Wiltshire,[5] also caused by gall-stones, is interesting in that the accumulated mass caused displacement of the kidney, which was relieved by operation.

The ingestion of large quantities of fruit with indigestible skins and seeds may give rise to a form of enterolith, or "gastrolith," as C. H. Cargile[6] more properly calls it, for the mass accumulates and remains in the stomach. He reports two cases, in which what was practically a cast of the stomach was made by a mass of persimmon skins and seeds. He also refers to two other similar cases, showing that this condition may not be uncommon in the South.

There are also found in the intestines and sometimes in the stools small concretions whose central mass consists of undigested food residue or inspissated mucus, while the bulk of the material is composed of ammonium magnesium phosphate, or perhaps magnesium phosphate, but may include calcium phosphate or carbonate and occasionally calcium and magnesium soaps and albuminous matter.

E. Deetz[6] and C. H. Bedford[7] report cases of intestinal sand. A distinction is made between "true" and "false" intestinal sand. The latter owes its origin to undigested vegetable particles, occasionally coated with earthy salts. "True" intestinal sand is found chiefly in gouty patients and is composed mostly of lime salts. Bedford attributes this fact to the long-continued milk diet given in such cases.

The only true case of fecal enterolith that I can find in the literature since 1899 is that of Ferguson and Reuter,[8] and as the history resembles in certain respects that of my case, I shall give a brief resumé.

Ferguson and Reuter's Case.—Mrs. J., aged 30, multipara, housewife, was admitted to Dallas Hospital Jan. 3, 1903. Since 10 years of age she had suffered with severe paroxysmal colic. She remembers at that time a small lump the size of a marble on the right side. This has never disappeared, but has gradually increased in size. Twelve years ago, at the age of 18, she was operated on in a Tacoma Hospital for tumor, but this was not removed. She was later informed that the intestines were too much involved to permit such a procedure.

On admission she had colicky pains in right hypogastric and inguinal regions, obstinate constipation, headache, nausea and vomiting. The abdomen was rigid and greatly distended.

Jan. 16, 1903, after treatment by ice-bags, purging,[8] enema, etc., the abdominal distention was sufficiently relieved to disclose a hard mass the size of a pear, freely movable within the intestine. Owing to its extreme hardness, a foreign body was suspected and a tentative diagnosis of enterolith was made. This was proved correct at operation, when the mass was found lying in the lumen of the ileum, about 15 inches from the ileocecal valve. Above the mass the intestine was dilated to twice its normal caliber and below contracted to one-third its normal size. The mass lay in a symmetrical, fusiform dilatation of the intestine, in which it was quite freely movable, acting as a ball-valve.

The specimen weighed 3½ ounces and measured 2½ inches in width and 3½ inches in length. It was composed of vegetable matter and salts with what appeared to be a large hazelnut nucleus. Recovery was uneventful.

My case reported below presents several interesting features, that is, the size and character of the enterolith, the absence of intestinal obstruction at any time, the symptom-complex leading to a mistaken diagnosis, the age and mental condition of the patient and her subsequent history.

Author's Case.—D. K., Russian, aged 17, single, shirt-waist maker, was admitted to the service of Dr. Taylor at Fordham Hospital on July 12, 1912. Nothing could be learned of her family history. Her parents were of the very poor peasant class of Russia.

*Personal History.*—The patient recalled no diseases of childhood, but had always been anemic and weak, with poor appetite and constipated bowels. Menstruation began one year ago, her periods being irregular in duration and occurrence and accompanied by severe pain. Patient lives in a poor hygienic and moral environment. At the age of 10 she first noticed a swelling of the abdomen in the hypogastric region. This tumor has gradually increased in size, has caused no pain, but at intervals has been slightly tender. Up to four months ago she had suffered from severe constipation, but since that time she has had large and copious movements. Her menstruation ceased entirely four months ago. She has had no vaginal discharge or uterine pain; denies sexual intercourse. There

## *New and Nonofficial Remedies*

The following additional articles have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Their acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on *investigation made by or under the direction of the Council*. Criticisms and corrections are asked for to aid in the revision of the matter before publication in the book "New and Nonofficial Remedies."

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that, so far as known, it complies with the rules adopted by the Council.

W. A. Puckner, Secretary.

*Slee's Antimeningitis Serum.*—Marketed in vials containing 20 Cc.

**ANTISTREPTOCOCCUS SERUM.**—(See N. N. R., 1913, p. 216.)

Slee Laboratories, Swiftwater, Pa. (The Abbott Alkaloidal Co., Chicago.)

*Slee's Antistreptococcic Serum.*—Marketed in vials containing 10 and 20 Cc.

## *Therapeutics*

### MORE IMPORTED (CANNED) MEDICATION

The prescriptions herein noted are criticized because they are considered by our medical journals of sufficient importance to be quoted[1] from French journals. Let us hope that such quotations will soon cease. The following combination is recommended to be given in "gouty migraine":

"R

| | | | |
|---|---|---|---|
| Extracti colchici cormi | | | |
| Quininae sulphatis | āā | gr. xlv | (3 grammes) |
| Pulveris digitalis | | gr. xxiii | (1.5 grammes) |

M. Fiant pilulae No. xxx.
Sig.: *One pill every evening.*"

Whether or not digitalis is advisable in gouty conditions is entirely dependent on the condition of the heart, and its use should not be advised without distinct statement of the conditions in which it is indicated, as many times digitalis is absolutely contra-indicated in gout.

The advisability of increasing the circulation in the brain by the use of quinin in gout might be seriously questioned. If the patient was plethoric, or had high blood-pressure or headache, quinin would seem inadvisable. Of course, it should be noted that the actual dosage here given is small, that is, 0.1 gm. (1½ grains) of quinin once a day, and it might not in this amount, cause any cerebral disturbance.

The value of 0.1 gm. (1½ grains) of the extract of colchicum root once a day is mythical; in fact, it is doubtful whether or not colchicum has any real value in chronic gouty conditions. In acute gouty conditions it seems to be of little value unless it produces free movements of the bowels. When colchicum is not prescribed in sufficient amount to cause free movements of the bowels, it is often combined with salicylic acid in some form, and it is the salicylic acid that is of benefit, although such benefit is often attributed to the colchicum.

Another prescription recommended "for the relief of acute attacks of gout" is the following:

"R

| | | |
|---|---|---|
| Quininae sulphatis | gr. xlv | (3 grammes) |
| Fluidextracti *aconiti* | ♏ xx | (1.3 grammes) |
| Extracti colchici *cormi* | gr. viiss | (0.5 gramme) |
| Extracti belladonnae foliorum | gr. iii | (0.2 gramme) |

M. Fiant pilulae No. xx.
Sig.: From one to four pills a day."

If aconite is to be of any value in a condition of acute gout, the preparation which is used must be an active one, and its administration must be *pushed until its* physiologic action is evident. To obtain the safe activity from aconite in such conditions as are present in acute gout it should be given in solution, and uncombined with other drugs, so *that its use may be stopped as soon as there is evidence of its full physiologic action.*

If one thinks that colchicum is of value in acute gout, its administration also must be pushed, and certainly one pill a day (although a latitude of from one to four pills a day is allowed) would be useless.

If quinin is of value in gout, let it be given alone, that its value may be demonstrated. Theoretically, a patient suffering from acute gout, if given quinin in doses of any amount, would have unpleasant cerebral disturbances added to his discomfort. There is no apparent physiologic or rational excuse for giving quinin to combat acute gout.

Of course, *it is immediately conceded that belladonna*, alone or in combination with aconite, would cause an abatement of peripheral pain; such *treatment* is not new. The only novelty is in the combination offered, and, since simplicity of medication is a desideratum and therefore each drug prescribed *should have positive* value, the quotation of so doubtful a mixture cannot be excused.

Again, from *France* come prescriptions for chorea. The writer quoted makes some good suggestions in regard to the general treatment of such patients, both in mild and in severe cases of chorea. He advises, "in mild cases," the following prescription:

"R

| | | | |
|---|---|---|---|
| Antipyrinae | | ʒ iiss | (10 grammes) |
| Tincturae belladonnae *foliorum* | | ♏ xl | (2.25 grammes) |
| Syrupii aurantii florum | | ℥ ii | (60 grammes) |
| Aquae destillatae | q. s. ad | ℥ v | (150 grammes) |

Misce."

Why is it necessary to tell an American physician that antipyrin can be dissolved *in syrup* of orange flowers and distilled water? Instruction *to this effect* may be given to second-year medical students; it is not necessary to copy such suggestions from France. The nonsense of prescribing distilled water should be emphasized, as investigations have *many times* shown that the distilled water of the drug shops contains more bacteria than ordinary water. If antipyrin is good treatment in chorea (and it may often be of value) let it be so stated, and the proper dose suggested.

The susceptibility of some persons, *even* children, to poisoning from belladonna should forbid its use in any such mixture as the preceding. Two very active drugs should rarely be combined in a mixture, as it may be wise to increase the dosage of one drug and to diminish that of the other. Belladonna could be ordered separately in the amount deemed advisable.

The writer quoted goes on to state that if the antipyrin does *not* prove successful in chorea, hydrated chloral in full doses should be given, and the following prescription is quoted:

---

[1] Prescriptions quoted appeared in New York Med. Jour., Oct. 11, 1913; Oct. 25, 1913.

"℞

| | | | |
|---|---|---|---|
| Chlorali hydrati | | ʒ ss-i | (2-4 grammes) |
| Potassii bromidi | | ʒ ¼-ss | (1-2 grammes) |
| Codeinae sulphatis | | gr. ⅔ | ( 0.04 gramme) |
| Syrupi | | ʒ v | ( 20 grammes) |
| Aquae destillatae | q. s. ad | ℥ iiiss | (110 grammes) |

M. Sig.: To be taken within twenty-four hours in tablespoonful doses."

To give hydrated chloral in severe cases of chorea is not new, neither is its combination with potassium bromid. To be compelled to give codein to a violent choreic patient is not a novelty. It is bad treatment to combine these three active drugs in one prescription. It certainly is not necessary to tell American physicians that these very strong depressomotors and narcotics may be given, if need be, to choreic children. Such "canned medication" as this is beneath the dignity of our best medical journals. The statement could be made that in severe chorea the physician may resort to chloral, bromids or codein, and the reader's intelligence would not be insulted.

Another instance of imported medication may be given. A physician of note (else he would not be quoted), while discussing the subject of "cardiac disturbances in chronic dyspepsia," advises in the treatment of palpitation, intermittencies, tachycardia, bradycardia, pseudo-anginal attacks, etc., besides a proper arrangement of the diet, the following prescription for constipation:

"℞

| | | | |
|---|---|---|---|
| Fluidextracti frangulae | | | |
| Fluidextracti rhamni purshianae, āā | ʒ vii | (25 grammes) |
| Glycerini | ʒ x | (40 grammes) |

Misce."

The criticism of this is simply that any physician knows enough to give a laxative without being furnished with a special prescription copied from Europe. Also, some pleasant-tasting, active preparation of cascara is just as good as this combination, or better. The action of frangula is similar to that of rhubarb, but is much harsher. The advised dose of the fluidextract of frangula is not far from 22 minims, while the Pharmacopeia gives 15 minims as the dose. The same dose of the fluidextract of cascara is prescribed; and both are to be administered in glycerin, which, unless well diluted, may produce nausea. The advice is given that a teaspoonful of this mixture be taken "in a little water" at bedtime. This prescription is unnecessarily disagreeable, and might easily act to the patient's disadvantage.

The next suggestion is that "a cool, moist compress, covered with some impervious material may be left on the epigastric and precordial regions over night." The particular one of the preceding cardiac disturbances for the relief of which this application should be made is not specified. Clinically, most patients with tachycardia or pseudo-anginal attacks will not allow any such application over the heart.

One pill made by the following formula is recommended to be taken at night:

"℞

| | | |
|---|---|---|
| Extracti hyoscyami | | |
| Fluidextracti valerianae | | |
| Zinci oxidi | āā gr. 4/5 | (0.05 gramme) |

Fiat pilula No. i."

The extract of hyoscyamus furnishes an atropin treatment. As the particular cardiac disturbance under treatment is not stated, one must object to the use of any form of atropin in palpitation or tachycardia, as in some persons atropin will cause an increased heart activity. The value of valerian is mythical, as has been repeatedly stated in these columns. In fact, it is doubtful if valerian has any activity whatever, except as a carminative. Zinc oxid should not be used internally.

The quotation states in addition that when cardiac discomfort occurs, an ointment, recommended by another noted European clinician, should be lightly rubbed over the precordium. The variety of cardiac discomfort is again not stated. Perhaps such specification is superfluous. The prescription follows:

"℞

| | | |
|---|---|---|
| Veratrinae | gr. iiss | ( 0.15 gramme) |
| Extracti opii | gr. xii | ( 0.75 gramme) |
| Olei terebinthinae rectificati | ʒ ss | ( 2 grammes) |
| Olei menthae piperitae | gtt. xii | |
| Adipis lanae hydrosi | ℥ i | (30 grammes) |

Misce. Fiat unguentum."

It should be noted that veratrin ointments are dangerous; both to the one on whom they are used and to the one who applies them. The value of the extract of opium when so used is probably nil. The turpentine would irritate, the peppermint would irritate and the veratrin might irritate. The opium and the wool-fat should be sedative. It is a question whether this ointment "lightly rubbed" on would irritate or soothe. Such a prescription should not be ordered.

The further advice is given that the patient with this cardiac discomfort should take a tablespoonful of the following sedative preparation every hour until the attack ceases. Again it is not stated for what kind of an attack the mixture is prescribed.

"℞

| | | | |
|---|---|---|---|
| Potassium bromide | | | |
| Cherry-laurel water | of each | ʒ iss | ( 6 grammes) |
| Syrup of ether | | ℥ i | ( 30 grammes) |
| Valerian distillate | | ℥ iiiss | (110 grammes) |

Mix and make into a solution."

This prescription from the standpoint of American medication, the preparations presumably being founded on the United States Pharmacopeia and National Formulary, is the limit of imported canned advice. An explanatory paragraph does state that the "syrup of ether contains 2 per cent. of ether and 5 per cent. of alcohol." The "valerian distillate is made by macerating one part of valerian with eight parts of water for twelve hours, distilling, evaporating to four parts, and filtering." Of course, it stands to reason that either the patient's first attacks of heart disturbance would be relieved or the patient would be dead before such a preparation could be made. But what valerianic nonsense! And just think of the odor of that drug shop during the preparation of this valerian distillate!

The syrup of ether is perhaps stimulant; it certainly is not sedative; and again we have this everlasting dash of cherry-laurel water. Will Europe ever cease worshiping at this shrine?

Last of all comes good old potassium bromid, which any physician on this side of the water would use, if he thought the indications called for it, without this elaborate quotation. The dose of the bromid offered is about 10 grains, and is administered every half hour until the attack ceases. Bromids are slow-acting drugs, and while the initial dose is small, if the heart did not soon right itself, a large amount of bromid would soon be circulating in the patient. It is better, when bromids are indicated in cardiac disturbances, to give a dose considered sufficient, and then to wait a number of hours before further administration, until the drug has had time to act.

## THE RESISTANCE OF VARIOUS NERVE-CELLS TO ANEMIA

The nervous system of higher animals is exceedingly sensitive to anemia or other physiologic conditions which involve a local lack of oxygen. Muscle tissue which has been supplied inadequately with this essential element or perhaps completely deprived of it for not inconsiderable periods of time may still show a satisfactory recovery of contractile power when the circulation is suitably restored and the resuscitating oxygen reaches the asphyxiated tissue-cells, but this is not the case with the nervous tissues. The nerve-cells of different classes and positions show differences in sensitiveness to anemia. Those of the cerebrum and cerebellum are unquestionably most readily damaged by oxygen starvation. There is evidence to show, for example, that eight minutes of complete anemia may permanently eliminate the function of some of the cells of the cortical areas. If the blood-supply there is wanting for more than twenty minutes it is rarely possible to discover restoration when the circulation is reestablished. In descending to the lower levels of the cerebrospinal nervous system the resistance to the detrimental effects of anemia or the immunity from permanent damage by lack of oxygen increases appreciably. In sequence the cells of the spinal bulb, the spinal cord and the spinal ganglia, respectively, appear to withstand anemia for longer and longer periods, so that a cessation of the circulation for eight or ten minutes may be of minor significance and permit of prompt complete recovery when the blood-supply is restored. Anemia of the spinal cord for an hour, however, is reported to be sufficient to cause necrosis of all the nervous elements.

A growing appreciation of the foregoing facts helps to explain the unfortunate outcome of conditions, as for example those following the oxygen starvation induced by carbon monoxid or coal-gas poisoning, in which there is acute oxygen want. Certain resulting permanent paraplegias are included in this group. The permanent disastrous results of oxygen want in the nervous retina induced by obstruction of the retinal vessels belong in the same category. Whether there are other neurons in the body which have a greater hardiness than those of the cerebrospinal axis, as just cited, has not hitherto been determined, though there have been intimations that some of the outlying cells, such as those of the sympathetic ganglia, are more stable in the absence of their blood-supply.

The persistence with which portions of the small intestine will exhibit rhythmic contractility long after their removal from the body, if they are treated with an oxygenated restorative like warmed Ringer's solution, suggests that their nervous supply, or more specifically the cells of the myenteric plexus, are exceptionally resistant to anemia. The basis for this assumption of survival of the nervous elements is the generally accepted evidence that rhythmic contractions of the alimentary canal do not occur if the plexus is wanting.[1] Quite apart from the purely theoretical aspect of the question, the determination of the degree of resistance of the intrinsic neurons of the alimentary tract to anemia and their limits of endurance are of interest in connection with the possibility of continued functioning after the interference with the circulation in surgical states such as hernia and intussusception.

An experimental inquiry conducted in the Harvard laboratory of W. B. Cannon, to whom we are already indebted for some of our fundamental knowledge of the alimentary tract, has furnished the basis for an intelligent appreciation of the points at issue in relation to the intestine.[2] According to these findings, if the vessels supplying parts of the alimentary canal are ligated, the tissues become edematous and purple, but may not be completely anemic. After this condition has persisted for six or seven hours such regions may recover normal activities, and, on being examined histologically, show nerve-cells with normal appearance. If complete anemia is produced by suitable compression, the condition may last as long as three hours and normal motility may still be restored. A persistence of compression anemia for three and one-half hours or longer, however, almost invariably results in loss of function and disappearance of nerve-cells in the compressed parts.

Cannon and Burket point out that the continued existence of the cells of the myenteric plexus after three hours of complete anemia — two hours longer than the cells of the sympathetic ganglia — reveals them as the most hardy nerve-cells thus far found in the body. Incidentally, it is worthy of emphasis that the concomitance of persistence or loss of function with persistence or destruction of nerve-cells lends new support to the contention that the spontaneous contractions of the alimentary canal are of nervous origin.

## THE WASHINGTON ANTIVIVISECTION CONGRESS

The third Antivivisection and Animal Protection Congress has been in session in Washington during the past week. As the name indicates, the congress has represented two interests. So far as it was an animal protection congress, all could heartily support it, even the "vivisectors" themselves, for no men have done more to protect animals from pain and disease than they. But so far as it was an antivivisection congress it was hostile to the very means which have proved most potent for alleviating the suffering of man and the lower animals as well. Under these circumstances it is impossible to judge the value of the lists of bishops, generals, senators, clergymen, governors, members of Congress and other public men widely advertised as vice-presidents of the congress, because it is impossible to know on which aspect of this two-faced organization they were looking when they permitted the use of their names.

[2] Cannon, W. B., and Burket, I. B.: The Endurance of Anemia by Nerve-Cells in the Myenteric Plexus, Am. Jour. Physiol., 1913, xxxii, 247.

Most prominent among the foreign members was the founder of these congresses, the widely heralded Miss Lind-af-Hageby, whose false statements a decade ago cost Coleridge $25,000 in his suit with Bayliss, and whose attempt this year to refute the charges that she was "a deliberate and systematic liar, and that her antivivisection propaganda had been carried on by a systematic campaign of falsehood," resulted in a prompt verdict against her. Her present contention is that more is to be expected for human life and welfare from hygiene and sanitation than from drugs and surgery. That practically all the modern practice of hygiene and sanitation is firmly based on the results and methods of "vivisection" is a fact which she seems to have overlooked.

The Rockefeller Institute, which in the short period of its existence has given the medical profession an effective means of combating cerebrospinal meningitis, a new method for the diagnosis of syphilis and devices for artificial respiration in anesthesia and shock, not to mention other important discoveries, was the chief target for vilification. It was designated by various speakers as a "chamber of horrors," as a "working model of hell," and as the crown of a "toppling mass" of wealth, "tainted by lying, stealing, arson and murder."

The most sensational claim made at the meeting was that not uncommonly physicians inoculate unsuspecting persons, often children and other dependents, with the germs of disease, solely for experimental purposes. This statement has been published with big head-lines in newspapers in all parts of the country. The evidence for it consisted in citing once more instances which have repeatedly appeared in antivivisection literature, and have repeatedly been shown to be false or without professional support. The "poisoning" of insane patients with thyroid extract was again mentioned, although the crafty deception in this charge has been made clear at least twice in the past twelve years.[1] The spraying of the nose and throat of patients with "poisons of diphtheria, small-pox, scarlet fever or consumption" was again instanced, although it has been disclosed that the person who confessed to having done this had also confessed that he had no standing in the medical profession, and, indeed, was quite in agreement with many antivivisectionists in disbelieving that bacteria cause disease.[2] The use of luetin was again described[3] as the "inoculation of the germs of a vile incurable disease," although it has been carefully shown that luetin was first proved wholly innocuous by injections into animals and into the discoverer himself, as well as into other physicians who volunteered for the test, and not until then was used for diagnostic purposes.

The public should definitely understand that the medical profession wholly repudiates and regards with abhorrence the employment of any procedure whatever which is in any way likely to injure rather than to benefit a patient who has entrusted himself, or who has been entrusted, to a physician's care. Such action would be absolutely at variance with the prime object of medical service—the welfare and the restoration of the sick.

Fortunately, the lay press is beginning to understand the unreliability of antivivisectionist assertions. Various papers have commented on the "virulence and nonsensical folly" of the misstatements and misrepresentations of antivivisectionists, have recognized them "as peculiarly impervious to the facts," have asserted that they "wilfully hide the serious purpose underneath the experiments on animals," or have flatly declared that they are "promulgating the most outrageous falsehoods about men whose lives are devoted as unselfishly and as efficiently to the service of humanity as any that could be mentioned." Even one of the speakers at the congress was moved to urge his hearers to "stick to the facts" and to "cease making wild statements which they could not prove." Let us hope that some day they may do so.

## IN WHAT FORM ARE PROTEIN DIGESTION PRODUCTS ABSORBED?

The idea that the products of the digestion of protein are regenerated into blood proteins as they pass through the alimentary wall in the course of their absorption has so long dominated the teaching of physiologists that it has not been easy to become adjusted to an entirely new doctrine in respect to the fate of these foodstuffs. The stubborn facts against which all attempts at theorizing have sooner or later stumbled are that ingested proteins disappear from the lumen of the digestive tract somehow in the course of alimentation; their nitrogenous end-product, urea, appears in a few hours in the urine; and what happens to bridge the gap between the beginning and end of this important chapter in physiology has almost completely eluded discovery, and therefore given room for a play of speculation.

It was as easy as it was inconclusive to assume that a portion of the food proteins or their derivatives may be built up in the cells lining the alimentary canal to form blood proteins, so that this organ would have to be regarded as an *important blood-forming organ.* The other extreme of hypothesis found its expression in the view that probably a major *portion of the protein does not reach the tissues at all* as a nitrogenous compound, but undergoes deamination in the intestinal wall, the nitrogen being rapidly carried by the portal circulation to the liver and converted into urea, and *thereupon* excreted by the kidneys, while the non-nitrogenous moiety is carried to the tissues, to which it serves as an important and ready source of energy. If we seek for the underlying reason why recourse was had to either of the preceding assumptions (for which it must in fairness be admitted that there was something more than speculative justification), it doubtless rests in the fact that no convincing evidence of the presence of nitrogenous digestion fragments in the blood after a protein meal was forthcoming. Every now and then some one announced the discovery of them, only to have its reality denied in a succeeding publication. So competent a chemical investigator as Abderhalden has in the past been unable to admit that nitrogenous protein digestion derivatives are present in the blood in amounts indicative of any routine physiologic function.

[3] Jour. Zoöphily, 1913, xxii, 4.

The aspect of the subject has become changed, however, by the advent of new and more delicate methods of blood analysis. To some of these reference has been made here in the past.[1] The earlier work of Delaunay[2] was followed by the noteworthy experiments of Folin and Denis[3] and of Van Slyke and Meyer,[4] all indicative of an indisputable absorption of *amino-acids* as such *from the alimentary tract.* This evidence that the protein products truly reach the blood-stream as amino-acids and are presumably carried to the tissues where they may be reintegrated into the proteins characteristic of each tissue or finally disintegrated with resultant production of the end-product urea has again been strongly fortified by new contributions from London's laboratory in St. Petersburg.[5] These show that only a few minutes after the introduction of an amino-acid like alanin into the intestine an increased content of aminonitrogen is detectable in the blood of the jugular vein, that is, the general circulation. Furthermore, during the digestive cycle in animals the proportion of aminonitrogen increases not only in the portal blood, but also in the peripheral circulation — less, as a rule, in the latter than in the former. Such evidence must be taken as an unmistakable indication of the current drift. The amino-acids are absorbed as such; and so they play their rôle in the nutritive processes. It has at length become necessary to readjust our theories to the facts of experiment and observation.

## OCCURRENCE OF TUBERCLE BACILLI IN THE CIRCULATING BLOOD

A great deal of work has been done during recent years on the question of the occurrence of tubercle bacilli in the blood of tuberculous patients. Two methods have been used, namely, the direct examination of the blood in stained preparations and the inoculation of guinea-pigs with blood. The results obtained by different investigators are in each case widely divergent, some having high percentages of positive results, others almost or wholly negative results. Some even report finding bacilli in the blood of healthy persons, who at least were not suffering from any active tuberculosis. In certain series of observations in which both methods were used, the microscopic examination of the blood gave from 60 to 100 per cent. of positive results, while the inoculation of guinea-pigs gave only an occasional positive result, and yet the latter method is recognized as by far the more sensitive and reliable of the two.

There are also, of course, observations in which closely concordant results were obtained, as for instance, those recently reported by Klopstock and Seligmann.[1] These investigators injected guinea-pigs with the sediment of from 5 to 15 c.c. of blood from forty-nine patients with pulmonary tuberculosis in various stages, but in no case did any inoculation tuberculosis develop. In no case in this series did the examination of blood preparations reveal bacilli that could be accepted as unquestionable tubercle bacilli. Before the sediment was injected it was treated with antiformin and then washed.

How is this divergence of results to be explained? As regards the results of microscopic examination alleged as positive, we know that, in some cases at least, saprophytic acid-proof bacilli present in the water or solutions used have been mistaken for tubercle bacilli. It is possible that precipitates and other artefacts have been so mistaken also. Now with respect to the animal inoculations it should be noted that the amount of blood used, the number of animals inoculated and the kind of cases of tuberculosis from which the blood was obtained have not been the same, so that the results really are not comparable. It is also evident that grave errors have been made by some workers in not exercising adequate care in the study and interpretation of the alleged tuberculous lesions in the guinea-pigs. In other words, results reported as positive do not stand the tests when judged according to the criteria applied to inoculation-tuberculosis. At all events, the results so far recorded of observations on the occurrence of tubercle bacilli in the circulation in tuberculosis are so contradictory and in many cases so manifestly unreliable that no definite conclusions are permissible. The work has not given us any methods of value in diagnosis, nor has it given us any new views as to the genesis of tuberculosis.

### THE PRESERVATION OF MILK BY DRYING

In the attempt to furnish milk to the consumer in a form free from the objections which hygienic considerations are yearly interposing in greater degree, one of the chief stumbling-blocks lies in the necessity of keeping the nutrient fluid fresh between the times of milking and of its delivery to the home. The problem of the modes of preservation, involving the questions of the application of heat to the raw product, the use of chemical preservatives, or the subjection to low temperature, has given rise to some acrimonious debate and has been the occasion for not a little legislation attempting to regulate the practices concerned. All of the schemes proposed or in use owe any alleged efficiency to such potency as they may exhibit in the direction of inhibiting or destroying the growth of micro-organisms. All of the proposed modes of preserving milk in transit have serious limitations in respect either to effectiveness or to expediency and cost. In view of this it seems strange that greater effort has not been devoted to perfecting some more suitable plan, in particular the obviously promising scheme of desiccating milk.

The concentration of milk by evaporation in the air was attempted more than a century ago. The first really practical method was devised by Mr. Gail Borden of White Plains, N. Y. Acting on a suggestion made by Horsford, he successfully evaporated milk at a low temperature under reduced pressure, and in 1856 obtained a patent for his process of preparing "condensed" milk, as it was subsequently termed. The lack of legal restrictions soon permitted the use of nutritively inferior grades of milk in the production of condensed milk, so that for many years poor qualities prepared from skimmed milk were freely sold to the ignorant customer. From the point of view of the danger of milk as a source of infection, it is doubtless true that there are advantages in condensed milk which are not always inherent in the fresh product. Delépine is said to have proved conclusively that tubercle bacilli, added purposely to milk before concentration, are invariably killed in the process of evaporation.[1] Condensed milk, however, is by no means always germ-free, and living organisms have been found in considerable number in commercial samples, although the species which were isolated were not pathogenic.[1]

The chief objection which has been raised to the widespread use of the more easily conserved condensed milk in place of the readily deteriorating fresh milk has been derived from the field of infant-feeding. Whether or not it be fundamentally justified, there is nevertheless a strong belief prevalent, based on apparently substantial grounds, that children fed on condensed milk are less resistant to the encroachments of disease than those brought up on fresh milk. Furthermore, condensed milk will deteriorate like fresh milk if it is diluted and then exposed to the chance of bacterial contamination.

Since the early years of the present century attempts have been made to carry the desiccation of milk still further than is done in the case of the thick, viscous condensed milk which already is concentrated enough to be a poor culture-medium for micro-organisms. The presence of fat has interposed the greatest difficulty to the complete drying of milk. Three successful processes for the manufacture of dried milk are in actual use.[2] All of them are protected by general and subsidiary patents which make it difficult as yet to assign a universally recognized name to the procedures. In the Ekenberg process the milk is sprayed under constant pressure on the inner surface of a rotating steam-heated cylinder. The milk is thus dried in partial vacuum, at a comparatively low temperature. A more frequently employed process, common in the production of cheaper grades in the United States, sprays the previously concentrated milk on the exterior highly polished surfaces of revolving steel drums. Here it is almost instantaneously dried at a temperature of 230 F. and then scraped off by sharp knife-blades. In the Bénevot-de-Neveu process an entirely different product results. The milk is first concentrated in a vacuum and then sprayed under great pressure into a large drying-chamber where the cloud of finely divided particles is surrounded by a current of hot air and thereby instantly dried. The result is a powder in which many of the physical and chemical properties of the original milk are retained.

The chief objection to most of the material prepared in this way lies in the less agreeable flavor of the dried product. There is every reason to believe that this can be improved with increased attention to the technic, especially the temperatures applied in the different stages and the containers employed. Desiccated milks have already begun to receive attention in the clinic of infant-feeding.[3] This is the severest test to which it can be put. Economy, cleanliness, convenience and hygienic considerations all suggest that high grades of dried milk are entitled to careful investigation for the possibilities which they present. A study of the markets shows that they have already made an inroad into the culinary departments of many institutions and homes.

**Psychiatry.**—Psychiatry not only enters into intimate contact with all the fundamental sciences of medicine and biology in general, but also touches on the social and moral sciences. On all it imposes problems, from all it requests data.—Lugaro, Modern Problems in Psychiatry.

# *Current Comment*

## ANOTHER "CANCER CURE"

A few days ago some of the Denver newspapers contained full-page advertisements of a "cure for cancer." The public was told: "The International Skin and Cancer Institute of Denver claims to have the *only* reliable treatment for cancer in existence. It claims that the remedy it possesses is the *only cure* in the world." The exploiter of this, the latest of cruel frauds, is one John D. Alkire, who, so far as we can learn, has neither medical nor pharmaceutical knowledge. What the "cure" is supposed to be, we do not know; neither, for that matter, is it necessary to know. Certain it is that the thing is a fraud — a cruel fraud, a damnable fraud. It is no excuse to say that Alkire is honestly convinced that the stuff he is selling is a cure for cancer. His conviction merely makes him that much more dangerous and gives him greater potentialities for harm. From its method of exploitation it is impossible to absolve Alkire from the suspicion, at least, that he is not acting in good faith. He claims to have lost both his father and his mother from cancer. If, therefore, he was absolutely convinced that he had the only cure known for this fearful scourge, it is hardly conceivable that he would monopolize the secret of it for the dollars to be made in exploiting it. Alkire and those associated with him will doubtless make money. Those afflicted with cancer, and those who believe themselves to be afflicted with cancer, will flock to Denver for the cure. Of those who rely on Alkire, the actual victims of the disease will, of course, die, but there will be the usual proportion of recoveries from non-malignant sores that will be heralded as "cures." This is the history of every fraudulent "cancer cure." Among the first beneficiaries of Alkire's inhuman business are those Denver newspapers that sold their pages to give publicity to this lying message to the unfortunate sufferers from cancer. To the honor of Denver be it said, some of its newspapers refused to accept Alkire's advertisement.

[After the preceding was in type a proof was sent to a Denver correspondent. Apparently, it was shown to some one connected with the Alkire concern, for on December 15, The Journal received the following telegraphic day letter from Denver:

> "We have learned of your proposed article to be published under title of Current Comment "Another 'Cancer Cure'" in which you make an unwarranted attack upon John D. Alkire and the International Skin and Cancer Institute Company. We wish to advise you that we consider this communication libelous, damaging and wholly unwarranted and that we will attempt to hold you responsible in damages if the communication is published and circulated in that form.—John Horn Chiles, John A. Deweese, Attorneys for John D. Alkire and the International Skin and Cancer Institute Company."

The Journal is not given to publishing matter for the purpose of injuring any one. Neither is it in the habit of being intimidated by threats of lawsuits. The comment on Alkire's "cancer cure" was written for one purpose only: that of attempting to offset in some small degree the publicity that had been given, through a portion of the Denver daily papers, to as cruel and inhuman a fraud as we know of — an alleged cure for cancer — and to warn the public from placing any faith in it. This being the purpose, The Journal is not to be turned from its course by threats of reprisal.]

## NEWSPAPER COMMENT ON ANTIVIVISECTION

We comment elsewhere on the recent antivivisection congress in Washington. It has been interesting to notice the attitudes taken by the newspapers. In general, those commonly classed as "yellow" have sided with the antivivisectionists, although in a somewhat half-hearted way, at the same time giving prominence in glaring headlines to the false, and therefore sensational, statements of these misguided enthusiasts. On the other hand, the great mass of newspapers, in their news pages as well as editorially, have tried to represent the real facts. The editorial comments in some instances have been excellent and have shown appreciation of the true conditions. Typical of these is one in the Boston *Herald*, which, under the title "Those Who Will Not See," says: "At the International Antivivisection Congress now in session in Washington, time-honored falsehoods are being rehearsed. Antivivisectionists are peculiarly impervious to facts. Perennially, they assert that animal experimentation has never accomplished anything." It continues with a series of paragraphs setting forth the great benefits to humanity resulting from animal experimentation, which has reduced the mortality in diphtheria from over 50 per cent. to practically nothing; has found a certain preventive for lockjaw; has discovered the Pasteur treatment for hydrophobia, and is daily uncovering great truths which must eventually bring to light cures for cancer, infantile paralysis, tuberculosis and other scourges of mankind which have hitherto baffled the scientists. It then continues: "But all this mass of evidence rolls from the antivivisectionists like water off a duck's back. And when Miss Lind-af-Hageby, the most audible of the assembled humanitarians, suggests sarcastically that scientists should try the experiment on themselves, she overlooks, from the depth of her ignorance, the long roll of honor of men and women who deliberately and unflinchingly risked and gave their lives in the cause of science."

## A PAMPHLET ON QUACKERY

The campaign of the Chicago *Tribune* against quacks operating in and from Chicago, has been referred to at various times in these pages. The *Tribune's* articles have had a far-reaching effect. The interest of public and press alike has been awakened. But quackery is about the same wherever we find it, from New York to San Francisco, from Portland to New Orleans. The facts brought out by the *Tribune*, therefore, are just as pertinent to the public generally as they are to the citizens of Chicago—and they will be as much to the point five years from now as they are to-day. Newspaper campaigns must, in the nature of the case, be more or less evanescent. The memory of the public is notoriously short. For this reason The Journal obtained permission to reprint the *Tribune's* articles in pamphlet form and thus put the material in a comparatively permanent form. The result is a booklet of 142 pages.[1] It should be in the hands of every physician to show those of his patients who are likely to fall into the hands of medical charlatans. Written as it is, by newspaper men, and containing as it does, the actual, first-hand experiences of the *Tribune's* investigators, it tells a story that is at once interesting and enlightening. The *Tribune* has turned on the light; we hope that the noisome pictures disclosed thereby may be given the widest possible publicity.

## *Medical News*

### ALABAMA

**Personal.**—Dr. Alf F. E. Thomas, Birmingham, was painfully injured in a collision between motor cars December 6.

**New Society Formed.**—The Alabama Society of Moral and Sanitary Prophylaxis was organized at Birmingham December 29. George H. Denny of the University of Alabama was elected president; Dr. George Petrie, Auburn, a vice-president, and Dr. William W. Dinsmore, Montgomery, secretary.

**Health Campaigning.**—Dr. William H. Sanders, Mobile, state health officer, and Dr. Philip B. Moss, Montgomery, director of the State Pasteur Institution, inaugurated a health campaign in Henry County the second week in December and in the succeeding week conducted a similar campaign in Houston County.

**New Staff Appointed.**—At a meeting of the board of directors of the Elizabeth Duncan Memorial Hospital, Bessemer, the following staff was appointed: Dr. Thomas F. Robinson, chief of staff; Dr. Samuel E. Grout, consulting surgeon; Dr. William Waldrop, oculist, and emergency staff, Drs. R. W. Waldrop, Carl A. Harris, Thomas C. Donald, James C. Berry and Edward P. Lacey.

**New Officers.**—Blount County Medical Society: president, Dr. Wilson T. Cantrell, Blount Springs; secretary-treasurer, Dr. Jesse T. Hancock, Oneonta.——Morgan County Medical Society at New Decatur, December 6: president, Dr. Arthur M. White, Hartselle.——Chilton County Medical Society at Mountain Creek: president, Dr. Julius P. Hayes; secretary-treasurer, Dr. Thomas J. Marcus, both of Clanton.——Dallas County Medical Association at Selma, December 3: president, Dr. Thomas G. Howard; secretary, Dr. Clarence C. Elebash, both of Selma.——Hale County Medical Society at Greensboro: president, Dr. Jacob Huggins, Newbern; secretary-treasurer, Dr. Charles A. Poellnitz, Greensboro.——St. Clair County Medical Society at Odenville, December 3: president, Dr. James W. Wood, Springville; secretary-treasurer, Dr. J. R. Chandler, Odenville.——Etowah County Medical Society at Gadsden, December 3: president, Dr. James H. Wood, Attalla.——Calhoun County Medical Society at Anniston, December 2: president, Dr. James C. Moore, Anniston; secretary, Dr. Jackson W. Landham, both of Anniston.——Madison County Medical Society at Huntsville, December 1: president, Dr. Charles E. Blanton, New Market; secretary-treasurer, Dr. Edgar Rand, Huntsville.——Jefferson County Medical Association at Birmingham, December 1: president, Dr. James M. Mason; secretary-treasurer, Dr. Harry P. Shugerman, both of Birmingham.——Lee County Medical Society at Opelika; president, Dr. Abijah B. Bennett; secretary-treasurer, Dr. O. Velpeau Langley, both of Opelika.——Montgomery County Medical Society at Montgomery: president, Dr. Fred W. Wilkerson; secretary, Dr. Paul S. Mertins, both of Montgomery.

### CALIFORNIA

**To Help Convalescents.**—The auxiliary to the University of Stanford Clinic, at a meeting recently held at Lane Hospital, San Francisco, effected a permanent organization to care for patients after their discharge from the hospital.

**New Officers.**—Yolo County Medical Society at Woodland, December 2: president, Dr. Claire Rason; secretary, Dr. Lula J. Beebe, both of Woodland.

**Psychopathic Ward Approved.**—The psychopathic ward of the Los Angeles County Hospital has been approved by the board of supervisors and formally accepted. Construction has begun on another wing of the Los Angeles County Hospital.

**Personal.**—Dr. Philip B. Fry, Benicia, has been appointed surgeon for the Southern Pacific system at Fort Costa.——Dr. Esther Rosencrantz has returned to San Francisco after several years of study abroad.——Dr. William F. Snow, Sacramento, secretary of the State Board of Health, has resigned on account, it is said, of differences with the State Board of Control.

### ILLINOIS

**Hospital Closed.**—The hospital at the Navy Training Station, Great Lakes, constructed by the government at great expense, is not to be reopened as it is considered an unnecessary expense to operate a large hospital when there are so few men stationed at the station.

**Personal.**—Dr. Frank Parsons Norbury, Springfield, and Dr. Albert H. Dollear, Hospital, have purchased Maplewood Sanatorium, Jacksonville, which was originally established by Dr. Norbury in 1901.——Dr. Lee O. Scott, Rockford, is reported to be seriously ill with typhoid fever in Canonsburg, Pa.——Drs. R. R. and H. F. McCarthy, assistant physicians at the Elgin State Hospital, have been transferred to the Dunning State Hospital.——Dr. Faith Spangler, assistant at the Dunning State Hospital, has been transferred to the Elgin State Hospital.

**New Officers.**—Adams County Medical Society at Quincy, December 8: president, Dr. Kirk S. Shawgo; secretary, Dr. Elizabeth B. Ball (reelected), both of Quincy.——Vermillion County Medical Society at Danville, December 8: president, Dr. Richard A. Cloyd, Catlin; secretary, Dr. E. Gordon C. Williams, Oakwood.——Madison County Medical Society at Alton, December 5: president, Dr. Edgar A. Cook, Upper Alton; secretary, Dr. Edward W. Fiegenbaum, Edwardsville.——Kewanee Physicians' Club, organized December 4: president, Dr. H. Nelson Heflin; secretary-treasurer, Dr. Francis O. Lowe.——North Central Illinois Medical Association at La Salle, December 9: president, Dr. George A. Dicus, Streator.

#### Chicago

**Medical Litterateur Dies.**—Carl H. von Klein, well known in Chicago as a collaborator of medical and collateral literature, as a translator and abstractor of medical articles, noted as an Egyptian scholar, whose work on the "Papyrus Ebers" was almost ready for issue, died in the Cook County Hospital, December 12, from diabetic gangrene, aged 71.

**Ball Addresses Medical History Society.**—The ninth meeting of the Society of Medical History of Chicago was held at the Hotel Sherman, December 11, when Dr. James Moores Ball, St. Louis, delivered an address entitled "Great Artists and Famous Anatomists," illustrated by lantern slides. Dr. William E. Quine, president of the society, was in the chair.

**Health Appropriation Cut.**—In the city budget for 1914 the commissioner of health asked for $1,160,278 for his department and the comptroller reduced this estimate by $220,497, leaving the recommended apportionment $2,870 less than last year. The health commissioner has made a vigorous protest, as he maintains that with this reduction the department will be dangerously crippled by lack of funds.

**Ball for Lying-In Hospital.**—The artists' fête to be given in the First Regiment Armory, January 9, is for the benefit of the new Chicago Lying-in Hospital, which is to be located on Fifty-First Street facing Washington Park. The building is to be six stories, fireproof, with six operating-rooms, five nurseries, two laboratories and four incubators. There will be beds for 105 mothers and their babies, and one-third of the hospital will be given up to free patients.

### INDIANA

**State Board Recommends Full-Time Service.**—In the annual report of the State Board of Health recommendations are made that health officers be paid sufficient salary so that they may give their entire time to the work of their offices and not be compelled to take private practice.

**Verdict of Not Guilty in the Knabe Case.**—William B. Craig, a veterinary surgeon of Indianapolis, charged with the murder of Dr. Helene Knabe, was tried at Shelbyville last week. After the prosecution rested, the judge instructed the jury to return a verdict of not guilty on account of insufficient evidence.

---

[1] "Men's Specialists Frauds," price 10 cents, post-paid.

**Hospital Notes.**—The commissioners of Hamilton County have authorized a $30,000 bond issue for the erection of a hospital at Noblesville. It was decided to purchase a building erected several years ago for a hospital by Dr. Samuel Harrell. ——Property valued at $22,000 has been presented to the hospital association at Washington, Ind.

**Personal.**—Dr. Charles S. Little, Petersburg, is reported to be critically ill.——Dr. John A. Salb has been appointed assistant police surgeon of Indianapolis.——The office of Dr. David H. Harold of Indianapolis was damaged by fire to the extent of $3,000 December 3.——Dr. David N. Foutz, Royal Center, was operated on for cataract recently, and is reported to be doing well.

**New Officers.**—Elkhart County Medical Society: president, Dr. Elmer E. Ash, Goshen; secretary, Dr. James A. Work, Jr., Elkhart.——Henry County Medical Society at Newcastle, December 4: president, Dr. Herman W. McDonald, Newcastle; secretary-treasurer, Dr. Walter C. Van Nuys, Newcastle.——Sullivan County Medical Society at Farmersburg: president, Dr. Robert H. Van Cleave; secretary-treasurer, Dr. James B. Maple, Shelburn.——Wells County Medical Society at Bluffton, December 2: president, Dr. Louis Severin, Bluffton; secretary-treasurer, Dr. Samuel A. Schoemaker, Bluffton.

## IOWA

**Personal.**—Dr. Guilford H. Sumner, Des Moines, entertained the state executive council at luncheon December 9.——Dr. George Hofstetter, Clinton, who has been seriously ill, is reported to be convalescent.——Dr. Ira Zeno Plunkett, Lewis, is reported to be seriously ill with cirrhosis of the liver.

**New Officers.**—Medical Society of Burlington, December 10: president, Dr. Albert C. Moerke; secretary, Dr. Ernest A. Hunt.——Clinton County Medical Society at Clinton, December 7: president, Dr. Harry C. Moffett, Clinton; secretary-treasurer, Dr. George A. Smith, Clinton.——Webster County Medical Society, December 2: president, Dr. William W. Bowen; secretary-treasurer, Dr. George B. Palmer (reelected), both of Fort Dodge.——Iowa City Medical Society, December 4: president, Dr. Charles S. Chase; secretary, Dr. Zella White Steward.——Cass County Medical Society at Atlantic, December 4: president, Dr. Ulysses S. Mullins, Atlantic; secretary-treasurer, Dr. Millard F. Stults, Wiota.——Monona County Medical Society at Onawa, December 3: president, Dr. John A. Thomson, Onawa; secretary, Dr. Frederick S. Spearman, Whiting.

## KENTUCKY

**Dr. Cecil Dead.**—The death of Dr. John G. Cecil, one of the best-known physicians of Louisville, occurred on December 12. A notice will appear in the obituary column next week.

**Individual Campaign for Hospital.**—In a one-man campaign for two weeks carried on by Lucas Brodhead to raise an endowment of $10,000 for the Woodford Memorial Hospital, Mr. Brodhead secured $9,075.

**Personal.**—Dr. J. T. Dixon has been elected president of the Owensboro Anti-Tuberculosis Association.——Dr. Ap Morgan Vance, Louisville, who was recently operated on at St. Joseph's Infirmatory, is reported to be convalescent.

**County Health Officers Assemble.**—A meeting of the county health officers of the state was held in Louisville, December 8 to 11. Among the out-of-town speakers were Dr. J. N. Hurty, commissioner of health of Indiana; Asst.-Surg. James H. Oakley, U.S.P.H.S., and Dr. Cressy L. Wilbur, Washington, director of the Bureau of Vital Statistics.

**New Officers.**—Fayette County Medical Society at High Oak Sanatorium, December 9: president, Dr. Carl L. Wheeler; secretary-treasurer, Dr. Lee C. Redmon (reelected), both of Lexington.——Oldham County Medical Society at La Grange, December 4: president, Dr. John E. L. Harbold; secretary-treasurer, Dr. Edgar D. Burnett, Anchorage (reelected).——Union County Medical Association at Morganfield, December 3: president, Dr. Carl P. Cottingham, Uniontown; secretary, Dr. Samuel L. Henry, Morganfield.——Henderson County Medical Association at Henderson, December 1: president, Dr. William A. Poole; secretary-treasurer, Dr. B. J. Neary, both of Henderson.——Fayette County Tuberculosis Association at Lexington, November 26: president, Dr. Ernest B. Bradley; vice-presidents, Dr. Frank H. Clarke and Dr. Orrin L. Smith; secretary, Mrs. J. C. Rogers.

## MICHIGAN

**Sanatorium Opened.**—The Ingham County Sanatorium, Lansing, was formally opened, December 1.

**Personal.**—Dr. Robert L. French, Detroit, has succeeded Dr. Edmond Quandt as physician of Wayne County.——Dr. Sylvester C. J. Ostrom, Saginaw, who has been seriously ill, is reported to be improving.——Dr. Hugh Cary, Detroit, is said to be critically ill.

**Cannot Care for Leper.**—The secretary of the State Board of Health has informed the health officer of Benton Harbor that the state has no provision for the care of lepers and cannot therefore assume responsibility for Jacob Goldstein. There is no state institution to which Goldstein can be admitted.

**New Officers.**—Bay County Medical Society at Bay City, December 9: president, Dr. Colin A. Stewart; secretary-treasurer, Dr. George W. Trumble, both of Bay City.——Kalamazoo Academy of Medicine, thirteenth annual meeting, December 9: president, Dr. James E. Maxwell, Decatur; secretary, Dr. Clarke B. Fulkerson, Kalamazoo.——Jackson County Medical Society at Jackson, December 4: president, Dr. William A. Gibson; secretary, Dr. George A. Seybold, both of Jackson. ——Calhoun County Medical Association's twenty-eighth annual meeting at Battle Creek, December 2: president, Dr. Elmer L. Eggleston; secretary-treasurer, Dr. A. Floyd Kingsley, both of Battle Creek.——Ingham County Medical Society at Lansing, November 20: president, Dr. Samuel Osborn; secretary-treasurer, Dr. Frederick M. Huntley, both of Lansing.

## NEBRASKA

**State Morgue Established.**—A state morgue has been established by the State Anatomical Board at the State Medical College, Omaha. Arrangements have been made to preserve the bodies of persons who die unidentified, for sixty days, so that there may be no difficulty about finding or identifying the bodies.

**Physician Exonerated.**—In the suit of John F. Neely against Dr. Homer Davis, Genoa, the case was taken from the jury by the federal judge, who found the plaintiff had no case. The suit was for $7,500 damages, the plaintiff claiming that a deformity of the finger was due to improper treatment by the physician. The case was handled by the legal department of the State Medical Association.

**Laboratory Building Dedicated.**—The new laboratory building of the University of Nebraska School of Medicine, Omaha, the first of the series of buildings to be constructed, was formally dedicated October 16. Addresses were made by Dean Wilson O. Bridges, Hon. John M. Grossman, former Dean Henry B. Ward, Regent F. L. Haller and Dr. Howard A. Kelly, Baltimore.——The University of Nebraska has opened a free dispensary at 1716 Dodge Street, Omaha.

**Additions to Faculty.**—Additions to the faculty of the University of Nebraska recently announced are Dr. Leroy Crummer, professor of clinical surgery; Dr. John P. Lord, professor of orthopedic surgery; Dr. Edson L. Bridges, instructor in medicine; Dr. William N. Anderson, instructor in physical diagnosis; Dr. Oscar T. Schultz, Cleveland, Ohio, instructor in pathology and bacteriology; Dr. A. A. Johnson, instructor in clinical pathology, and Dr. Claude Mitchell, assistant in physiology.

**New Officers.**—Lancaster County Medical Society at Lincoln, December 6: president, Dr. Henry J. Lehnhoff; secretary-treasurer, Dr. Harry Winnett Orr, both of Lincoln.——Adams County Medical Society at Hastings, December 3: president, Dr. Franklin Schaufelberger, Hastings; secretary-treasurer, Dr. Alma J. Chapman, Ingleside.——Tri-County (Brown, Keya Paha and Rock) Medical Society at Ainsworth: president, Dr. George O. Remy, Ainsworth; secretary-treasurer, Dr. James C. Tucker, Long Pine.

**Personal.**—Dr. Edmund B. Fulliam, Shelby, has been appointed division surgeon for the Union Pacific Railway. ——Dr. Benjamin R. McGrath, Grand Island, has leased the General Hospital for three years from the Grand Island General Hospital Corporation. The institution will be operated as in the past.——Dr. Tenny T. Harris, Omaha, was elected supreme vice archon of the Pi Beta Phi medical fraternity at its recent meeting in Minneapolis.——Dr. Solon R. Towne of Omaha sustained a fracture of the clavicle and a rib while endeavoring to quiet a fractious horse, October 23.——Dr. John H. Vance, Omaha, was operated on in Rochester, Minn., for the removal of gall-stones, October 9.——Dr. Davis, York, has been appointed pathologist to the Hastings State Hospital.

## NEW YORK

### New York City

**Biggs Resigns.**—Dr. Hermann M. Biggs has resigned his office of chief medical inspector in the Department of Health. Dr. Biggs has been in the service of the city for twenty-six years and it is to him that credit is largely due for keeping the Department of Health abreast of the times. His resignation is regretted on all sides.

**New Classification in Tuberculosis Clinics.**—The new classification and results of treatment recommended by the National Association for the Study and Prevention of Tuberculosis was recently brought up for discussion by the Health Department in response to a request from the secretary of the national association as to whether the Health Department regarded this classification as feasible for use in its clinics. The new classification, which it is believed offers many advantages over the old, will be adopted Jan. 1, 1914.

**Raising Funds for Washington Heights Hospital.**—A ten days' campaign for the purpose of raising $150,000 for this institution was begun on December 8 and is to be continued for ten days. During the first four days of the campaign $25,982 was raised. The hospital now occupies two made-over dwellings, from which it is soon to be ousted and the fund is for the purpose of erecting a permanent home for the hospital. Last year 7,000 cases were treated, 1,200 ambulance calls answered and 5,000 dispensary cases were treated.

**Sale of Mercury Regulated.**—The Department of Health has announced that restrictions have been placed on the sale of bichlorid of mercury. The amendment of the Sanitary Code which has been adopted reads as follows: "Bichlorid of mercury, otherwise known as corrosive sublimate, shall not be held, kept, sold or offered for sale at retail in the dry form except in colored tablets individually wrapped, the wrapper to have the word 'poison' in plain letters conspicuously placed, and dispensed in sealed containers of glass, conspicuously labeled with the word 'poison' in red letters." This ruling does not apply to tablets containing one-tenth of a grain or less of the drug.

**The Safety Exhibit.**—The first International Exhibit of Safety and Sanitation was opened December 11 and continued until December 20 in the Grand Central Palace. Among the features of the exhibition were exhibits of national governments. The United States showed how it cares for soldiers and sailors in times of peace and war, including a field hospital and ward rooms. The actual conditions of camp life were reproduced as regards sanitation, and preventive measures against typhoid fever and yellow fever. The Public Health Service showed the protective measures that are being enforced in mines. The British Home Office and the Board of Trade showed the government activities in England for protection in factories and workshops. Switzerland illustrated the methods that it has adopted for stamping out the white slave traffic. There are more than 350 delegates attending the sessions of the conference, which are held daily in connection with the exhibition.

**Babson's Tables on Medical Guesses.**—Roger W. Babson's charges, based on statistics from hospital records, accusing physicians of incorrectness in making diagnoses, have been refuted and explained by Dr. Sigismund S. Goldwater of Mount Sinai Hospital. Dr. Goldwater points out the fallacies in Babson's statistics and accounts for the high percentage of "bad guessing" by the fact that there are too few post-mortem examinations in this country. He favors legislation requiring such examinations in all public hospital death cases in order to give physicians the opportunity to correct their mistakes in similar cases that they may have in the future. Dr. Goldwater shows that in New York City post-mortem examinations are had on only from 7 to 24 per cent. of deaths, while in Europe the number ranges from 58 to 97 per cent. Dr. Goldwater also points out that many of the so-called discrepancies are not real but only apparent because the lay mind is not in a position to appreciate all the factors involved.

## NORTH CAROLINA

**Personal.**—Dr. Milton R. Gibson, Maxton, announces that he will remove to Raleigh, January 1, where he will limit his work to the eye, ear, nose and throat.——Dr. James W. Kornegay, Mount Olive, was stricken with cerebral hemorrhage in Goldsboro, December 8, and is reported to be critically ill.

**Dairies Must Be Sanitary.**—The supreme court of North Carolina, in the case of the City of Asheville against H. L. Nettles, dairyman, has sustained the Asheville milk ordinance, prescribing a license tax of one dollar per cow and specifying standard sanitation to be observed in the management of dairies and the marketing of milk.

**New Officers.**—Third District Medical Society, first annual meeting in Wilmington, December 3: president, Dr. James L. Nicholson, Richlands; secretary-treasurer, Dr. Earnest S. Bulluck, Wilmington.——Guilford County Medical Society at Greensboro, December 5: president, Dr. John A. Williams; secretary-treasurer, Dr. Parran Jarboe, both of Greensboro.——Seventh District Medical Society at Lincolnton, December 5: president, Dr. John B. Wright, Lincolnton; secretary, Dr. Robert H. Lafferty, Charlotte. The next meeting will be held in Concord.

## OHIO

**Place of State Meeting Fixed.**—The Ohio State Medical Association is said to have accepted the invitation tendered it by Columbus, and will meet in that city May 5 to 7, 1914, holding its sessions in Memorial Hall.

**Personal.**—Dr. Howard M. Francisco has been appointed assistant physician and pathologist at the Cleveland State Hospital.——Dr. Sherman Wolcott suffered a cerebral hemorrhage at his home near Gahanna, September 8.——The office of Dr. Frederick L. Lewis, Akron, was destroyed by fire, November 26.

**New Officers.**—Ashland Academy of Medicine, organized December 5: president, Dr. Robert C. Kinnaman; secretary-treasurer, Dr. Jacob Fridline.——Tuscarawas County Medical Society: president, Dr. Robert A. Goudy, Newcomerstown; secretary-treasurer, Dr. George T. Haverfield, Uhrichsville.——Montgomery County Medical Society at Dayton, December 5: president, Dr. Rufus C. Pennywitt; secretary, Dr. Charles C. McLean (reelected), both of Dayton.——Clark County Medical Society at Springfield, December 8: president, Dr. James E. Studebaker, Springfield.——Wyandot Medical Society at Upper Sandusky, December 4: president, Dr. George O. Maskey; secretary, Dr. Arthur N. Smith, both of Upper Sandusky.

**Society Proceedings.**—The Academy met at the Literary Clubrooms, Monday evening, December 15. The nominating committee submitted the following names of members to act as official candidates for the coming year: president, Dr. A. B. Thrasher; first vice-president, Dr. Sidney Lange; second vice-president, Dr. Dudley Palmer; secretary, Dr. C. T. Souther; treasurer, Dr. A. G. Drury. The program for the evening was one of particular interest. Dr. Paul G. Woolley read a paper on "Multiple Hyalo-Serositis"; Dr. Oscar Berghausen, on "Syphilis of the Liver"; Dr. E. C. Steinharter, on "Experimental Gastric Ulcer in the Rabbit."——Dr. J. Edward Pirrung was the host at the last meeting of the Obstetrical Society which met at the Alms Hotel December 11. A very interesting paper was read by Dr. Bonifield, dealing with "After-Treatment of Abdominal Section." A few of the many debatable theories advanced in the paper were early purgation following abdomnial section, denial of sedatives for the relief of pain and the substitution of hot water by mouth or rectum to take the place of ice for the relief of thirst. The paper was very freely discussed by every member present, after which a bountiful lunch was served.

### Cincinnati

**Prevention of Cancer.**—At the annual celebration of the Founders and Emory Memorial Day at the Ohio Mechanics' Institute a lecture was delivered, December 16, by Dr. E. Gustav Zinke on "Cancer, Its Cause, Prevention and Cure."

**Personal.**—Dr. Simon P. Kramer has been appointed professor of clinical surgery in the University of Cincinnati.——Dr. Henry L. Woodward has been appointed senior physician to the Cincinnati Hospital, vice Dr. Frederick Forchheimer, deceased.——Drs. S. Oscar Berghausen, Clement C. Fihe, Starr Ford and Arthur E. Osmond have been added to the junior staff of the institution.

**Councilor District Meeting.**—On December 8, the First Councilor District Medical Association held its annual meeting. Clinics were arranged at the various hospitals in the morning and in the afternoon a session was held in the amphitheater of the City Hospital, where addresses were made by the president, Dr. Herschel Fisher, Dr. A. W. Binckley of the Ohio State Liability Board of Awards, Drs. Martin H. Fischer and Sidney Lange, Cincinnati, and Dr. John T. Geraghty, Baltimore. The evening session of the society was held by invitation with the Cincinnati Academy of Medicine, and at this session addresses were delivered by Dr. George A. Fackler, president of the Ohio State Medical Association, and Dr. George H. Simmons, Chicago.

**Sex Education Discussed.**—At the meeting of the Medico-Civics Society, November 20, the paper of the evening was presented by Dr. Philip Zenner on "Sex Education in the Public School." The speaker treated the subject from the point of view of home instruction and school instruction, preferring the former and emphasizing the necessity for the latter, because of the unwillingness or inability of parents to undertake the task of imparting proper knowledge along these lines to their children. Dr. Elizabeth Campbell opened the discussion and urged that the teachers be especially trained for this work in order to be able to present the subject to their pupils in a proper and convincing manner. The general consensus of opinion appeared to be that while the necessity for sex education in the public schools is at once urgent and apparent, yet the matter is one that requires so much tact, special thought and preparation on the part of the educator that for the present, at least, it should be postponed.

## PENNSYLVANIA

**Hospital Building.**—The Mercey Hospital, Johnstown, plans to build a new administration and ward building, to cost about $50,000.

**Home for Incurables Needed.**—In the annual report of General Agent Bromley Wharton to the State Board of Public Charities, recommendation was made for the establishment of a state institution especially devoted to the care of cases of incurable diseases, such as cancer and other wasting disorders.

**Personal.**—Dr. F. B. Thomas has returned from Europe and opened an office in Dorranceton.——Dr. Richard G. Burns, Pittsburgh, has been appointed superintendent of the bureau of sanitation in the department of public health at Pittsburgh, vice Dr. H. K. Battey, deceased.——Dr. Charles J. Keim has been elected burgess of the borough of Cabasauqua.

**Library Presented to Medical School.**—The library of the late Prof. Ernest Ziesler, for many years professor of pathology at the University of Freiburg, purchased for the University of Pittsburgh by Mr. Richard Beatty Mellen was formally presented to the University at a meeting held in the University Club, Pittsburgh, December 5. The addresses of the evening were given by Dr. William H. Welch, Baltimore, and Mr. Harrison W. Carver, Pittsburgh.

**New Officers.**—Oil City Medical Club, December 5: president, Dr. Frank B. Jackson; secretary, Dr. Sylvester W. Sellew.——Physicians' Association of the Bethlehems, December 4: president, Dr. Milton H. Herbein, South Bethlehem; secretary, Dr. Christian A. S. Kemper, Bethlehem.——Jefferson Medical Club Alumni Association of Northeastern Pennsylvania at Scranton, December 4: president, Dr. James N. White, Scranton; secretary, Dr. Frederick L. Van Sickle, Olyphant.

**Health Commissioner Sues Town.**—State Health Commissioner Dixon on December 3, instituted suit against the town of Coudersport for the recovery of $145,000 in fines. It is charged that the borough failed to observe a decree of the governor, attorney general and commissioner of health directing it to "discontinue the discharge of sewage into a stream draining into the Allegheny River. A fine of $500, and a penalty of $50 a day for each day of failure to observe the decree is claimed.

### Philadelphia

**Bazaar for Ambulance.**—The Hospital of the Woman's Medical College held its seventh annual bazaar, December 6, the proceeds from which are to be devoted to the purchase of an ambulance.

**Personal.**—Dr. Hubley R. Owen has been reinstated as chief police surgeon of the city.——Dr. William Campbell Posey, who has been seriously ill with pneumonia, is reported to be convalescent.——Dr. Arthur Dare sailed for Europe, December 12.

## TEXAS

**Health Bulletin Adopted.**—Gaines, Hunt and Fayette counties have adopted the monthly bulletin of the State Board of Health as a supplementary text-book on health.

**Sanatorium Addition.**—The annex to the Scott and White Sanitarium, Temple, erected at a cost of $50,000, which is nearly ready for occupancy, will double the capacity of the institution which will then be able to accommodate two hundred patients.

**Personal.**—Dr. Bascom Lynn, superintendent of the State Tuberculosis Colony, Carlsbad, has resigned, to take effect January 1.——Dr. L. S. McKane, special representative of the State Board of Health, has returned after three months in Tampico, Mex.——Dr. Malone Duggan, San Antonio, is reported to be ill in Johns Hopkins Hospital, Baltimore.

**Quarantine Edict Revoked.**—The governor in a proclamation dated November 28 revoked his quarantine proclamation of April, 1913, which imposed certain conditions on all vessels from all ports south of 25 degrees north latitude and entering ports of this state, this proclamation to take effect on and after December 1. The section relating to entrance of vessels infected with contagious diseases into Texas ports will remain in full force, and quarantine is furthermore declared "against all person or persons infected or liable to be infected with small-pox, yellow fever, cholera, typhus fever, bubonic plague or other dangerous communicable diseases, whether within or without the state of Texas."

**New Officers.**—Grayson County Medical Association at Sherman, December 3: president, Dr. Otto Carl Ahlers, Sherman; secretary-treasurer, Dr. Davis Spangler.——McLennan County Medical Society at Waco, December 2: president, Dr. James M. Witt; secretary-treasurer, Dr. D. L. Eastland, both of Waco.——Jefferson County Medical Society at Beaumont, December 1: president, Dr. Louis Goldstein; secretary-treasurer, Dr. Wilbur F. Thomson, both of Beaumont.——Dallas County Medical Society at Dallas, December 1: president, Dr. Calvin R. Hannah; secretary, Dr. Royal S. Loving (reelected), both of Dallas.——Jasper and Newton County Medical Society at Kirbyville, November 25: president, Dr. B. A. Swinney, Newton; secretary, Dr. Dru McMickin, Kirbyville.——Trinity County Medical Society at Trinity, November 20: president, Dr. Charles H. Bradley, Groveton; secretary-treasurer, Dr. William H. Pope, Jr., Trinity.——El Paso-Big Springs Medical Association at Abilene, November 18: president, Dr. Granville T. Hall, Big Springs; secretary, Dr. W. R. Smith, Colorado.——San Antonio Academy of Medicine, organized November 10: president, Dr. Charles A. R. Campbell; secretary-treasurer, Dr. R. A. Roberts.

## VIRGINIA

**Presentation to Secretary.**—At a meeting of the South Piedmont Medical Society in South Boston, the third Tuesday in November, a handsome silver service was presented by the society to its secretary, Dr. George A. Stover, South Boston.

**The James Thomas Lectures.**—Dr. Jacques Loeb, director of the department of experimental biology of the Rockefeller Institute for Medical Research, conducted the thirty-fourth annual course at Richmond College under the James Thomas lecture endowment, December 11 and 12. The first lecture was on "Artificial Parthenogenesis" and the second on "Determinism in the Animal World."

**New Officers.**—Richmond Academy of Medicine and Surgery, December 9: president, Dr. Charles V. Carrington; secretary, Dr. Mark W. Peyser (reelected for the twenty-first term).——Medical Faculty of Petersburg, November 21: president, Dr. William C. Powell; corresponding secretary, Dr. George H. Reese; recording secretary, Dr. Leverett S. Early.——Roanoke Academy of Medicine: president, Dr. William L. Powell; secretary, Dr. William W. S. Butler, Jr.

## GENERAL

**Tri-State Association to Meet.**—The sixteenth annual session of the Tri-State Medical Association of the Carolinas and Virginia will be held in Wilmington, N. C., Feb. 18 and 19, 1914, under the presidency of Dr. Southgate Leigh, Norfolk, Va. Dr. Charles T. Harper, Wilmington, is chairman of the committee of arrangements.

**Soo Line Surgeons Hold Meeting.**—At the seventh annual meeting of the Minneapolis, St. Paul and Sault Ste. Marie Railway Surgical Association held at Milwaukee, December 5 and 6, the following officers were elected: Dr. John M. Dodd, Ashland, Wis., president; Dr. John Steele Barnes, Milwaukee, vice-president; Dr. John H. Rishmiller Minneapolis, secretary-treasurer (reelected), and Drs. John H. Rishmiller, Minneapolis; Chas. A. Steward, Duluth; Chas D'A. Wright, Minneapolis; Alexander J. McCannel, Minot, N. Dak., and John M. Crafts, Minneapolis, censors. Sault Ste. Marie, Mich., was selected as the next place of meeting.

**Infectious Diseases.**—During the first week in December contagious diseases have been reported, among others, from the following places: Diphtheria: Minneapolis, 160 cases; Litchfield, Minn., twenty-four cases; Augusta, Kan.; Wilkes-Barre, Pa.; Detroit, 200 cases; defective methods were found in the manner of releasing from quarantine, which was said to account for the spread of the disease. Dr. Edward H. Hayward, bacteriologist of the health department, resigned.

The two-culture method has been adopted: Woodland, Cal.; Grass Valley, Nev.; Davenport, Iowa. At Jefferson City, Mo., sixteen prisoners were barred from the state penitentiary on account of exposure to a case of diphtheria in the jail at St. Louis before being taken to Jefferson. Small-pox: In order to prevent the spread of the epidemic at Joliet, Ill., almost universal vaccination was enforced by the city and health authorities. December 2 Indianapolis had eight cases reported in forty-eight hours. Shelbyville, Ky., reports a number of cases. Walla Walla, Wash., has a number of cases. DeRidder, La., where compulsory vaccination has been enforced. Kansas City, Mo. Toledo, Ohio, where a third school has been closed on account of a few cases. At Dutzow, Mo., the school was closed. Scarlet fever: Liberty, Tioga County, Pa.; Wilkes-Barre, Pa.; Mount Pleasant, Pa., school closed. An outbreak occurred among the Indians on the Crow Reservation, Montana, and quarantine of the reservation was declared by the State Board of Health.

**Civil Service Examination.**—The United States Civil Service Commission announces an open competitive examination for medical assistant, for men only, on Jan. 12, 1914. From the register of eligibles resulting from this examination certification will be made to fill a vacancy in this position in the Bureau of Chemistry, Department of Agriculture, Washington, D. C., at $1,800 a year, and vacancies as they may occur in positions requiring similar qualifications, unless it is found to be in the interest of the service to fill any vacancy by reinstatement, transfer or promotion. The duties of this position will be to study the claims and representations made in conjunction with proprietary remedies, look up medical literature, assist in preparing cases, etc., under the Food and Drugs Act. A knowledge of French and German is desirable. Competitors will not be assembled for examination, but will be rated on the following subjects, which will have the relative weights indicated:

| Subjects | Weights |
|---|---|
| 1. General education and medical training.................. | 35 |
| 2. Practical or professional experience and fitness......... | 45 |
| 3. Publications or thesis ........................... | 20 |
| Total ........................................ | 100 |

Graduation from a medical school of recognized standing and at least three years' subsequent experience in the practice of medicine, or two years' subsequent experience in either pharmacological investigations or the actual examination of drug products with reference to the claims made therefor by manufacturers, are prerequisites for consideration for this position. If a thesis is submitted under Subject 3 it must present the results of original investigational work on the part of the applicant in some phase of medicine or pharmacology. Statements as to training, experience and fitness are accepted subject to verification. Applicants must have reached their twenty-fifth but not their forty-fifth birthday on the date of the examination. Under an act of congress applicants for this examination must have been actually domiciled in the state or territory in which they reside for at least one year previous to the date of the examination. This examination is open to all men who are citizens of the United States and who meet the requirements. Persons who meet the requirements and desire this examination should at once apply for Application Form 304 and special form, to the United States Civil Service Commission, Washington, D. C.; the secretary of the United States Civil Service Board, Post Office, Boston, Mass., Philadelphia, Pa., Atlanta, Ga., Cincinnati, Ohio, Chicago, Ill., St. Paul, Minn., Seattle, Wash., San Francisco, Cal.; Customhouse, New York, N. Y., New Orleans, La., Honolulu, Hawaii; Old Customhouse, St. Louis, Mo.; or to the chairman of the Porto Rican Civil Service Commission, San Juan, P. R. No application will be accepted unless properly executed and filed, in complete form, with the commission at Washington prior to the hour of closing business on Jan. 12, 1914. In applying for this examination the title "United States Civil Service Examination, Medical Assistant (Male)" should be used.

## CANADA

**Library to Be Established.**—The Medical Council of Saskatchewan has decided to establish a medical library at Saskatoon and not at Regina as originally planned.

**Typhoid in Halifax.**—Halifax, N. S., has been experiencing an epidemic of typhoid fever. An emergency hospital for fifty patients has been secured, and an investigataion is proceeding into the cause of the outbreak.

**Instruction in Tuberculosis.**—For the benefit of the students of the Manitoba Medical College, the provincial sanatorium at Ninette will be utilized for clinical instruction in tuberculosis. This is the first departure in this direction in Canada.

**Prize for Research Work.**—A prize to be awarded annually or biennially has been established in connection with research work in the University of Manitoba. It will be for the essay on the best work done in connection with physiology or physiological chemistry.

**Personal.**—Prof. J. George Adami, McGill University, Montreal, addressed the Denver County Medical Society December 12 on "Intestinal Stasis."—Dr. John Taylor Fotheringham, Toronto, was the guest of the evening at the annual dinner of the *Oxford County Medical Association, October 29.*

**Will Accept Registration Certificates.**—The Manitoba Medical Council has decided to accept for registration under the provisions of the Dominion Medical Act, all applicants who present a certificate of registration on the Dominion Medical Council register, whether the same has been obtained by examination or by virtue of ten years' previous practice in any province, subject only to proof of identity, and payment of the registration fee of $100.

**Hospital News.**—Toronto city council has made a supplementary grant of $8,272.20 to the Hospital for Sick Children. ——Forty-seven patients were treated at the Victoria Hospital, Fredericton, N. B., in October. One death occurred. ——The Royal Victoria Hospital at Barrie, Ont., has just completed its sixteenth year. During the past year 418 patients received treatment. There were thirty-nine births in the year and twenty-six deaths.——The General Hospital, Welland, Ont., treated 437 patients during the year ended September 30. Twenty-five deaths and seventeen births occurred. More room is to be provided for this hospital and a nurses' home in the immediate future.——Toronto has now a measles hospital with accommodation for thirty patients. It was formerly the Nurses' Home at the old General Hospital.——The Montreal Dispensary will erect a new building.——The central building of St. Boniface Hospital, Winnipeg, is to be rebuilt.——St. Paul's Hospital at Saskatoon, Sask., newly opened, has accommodation for 100 patients. The cost of the building was $175,000.——The Waddell Memorial Hospital at Canora, Sask., has been completed and Dr. Gray of Montreal has been appointed superintendent.—— Vancouver General Hospital will soon add an administrative building and nurses' home. The former is to cost $80,000 and the latter $115,000.

## LONDON LETTER

*(From Our Regular Correspondent)*

LONDON, Dec. 6, 1913.

### The National Insurance Act

The magnitude of medical services under the national insurance act is shown by some figures recently given by a member of the government, Mr. Churchill, who asserts that no greater administrative achievement has stood to the credit of the civil service of any country than the establishment in a few months of a tremendous universal system and organization of insurance. Although the act has been working for only nine months, 13,700,000 persons have been insured, and their affairs are being administered through 233 insurance companies and upward of 23,500 societies; 22,000,000 visits have been paid by 20,000 panel physicians, and nearly 12,000,000 cases have been treated. The cost of medical benefit has been $22,500,000. Sanatorium benefit has been provided for 36,000 persons.

The act is regarded by various sections of the profession with very different feelings. It cannot be denied that those engaged in industrial practice have benefited financially. Remuneration is much better than under the old contract practice of societies—nearly twice as much—and the physician is free from the domination of the clique which rules every lodge and has power to deprive him of his appointment because of some unreasonable charge by a member. Now if a patient is not satisfied with his physician, all he can do is transfer himself to the panel of another doctor. The increased remuneration obtained under the act has attracted physicians into industrial practice in such numbers that there is a shortage in other directions. Appointments under education and asylum authorities, which would have been sought by fifty applicants before, have been advertised in the medical journals for six or eight months without bringing a single answer, although the salaries have been doubled. Formerly young physicians were glad to take appointments at salaries ranging up to $1,500 a year. On the other hand, considerable dissatisfaction prevails in the ranks of those who have not accepted service under the act (non-panel physicians). They complain that their patients are compulsorily transferred to panel physicians, though they appear in many cases to have benefited instead of losing financially. This paradox is explained by the fact that at the time of the struggle of the British Medical Association with the government political feeling ran high, and the conservative press as well as a section of the profession held up to opprobrium those who would take service under the act, alleging that they were an inferior order of practitioners. Moreover, the large and unnecessary amount of clerical work thrust on physicians at the inauguration of the act proved most onerous and made inroads on the time required for professional work. The opposition press exaggerated the evil and represented panel physicians as so overwhelmed with work that they could not give proper attention to patients. The result was that the fact that a physician was not on the panel was a recommendation. He was considered to be a superior man, and to have sufficient time to attend to private patients. Though medical benefits under the act are working smoothly and the number of complaints is exceedingly small considering the enormous number of people involved, the panel practice is in many ways an improvement on the old contract practice; it still has some of the evils inseparable from contract practice. Time is wasted in attending hypochondriacs and others with very little the matter who wish to avail themselves of the free and unlimited drugging provided. The incentive to individual effort in the case of private patients is wanting. Examination tends to be perfunctory and treatment routine.

### Radium for Hospitals

At a meeting of the governors of the Middlesex Hospital, Prince Alexander of Teck announced that he had made a suggestion to the council of King Edward's Hospital Fund with the object of securing a more economical provision of radium for use in the London hospitals. In order to avoid the capital of these hospitals being drawn on for the purpose he asked the council to purchase a quantity of radium and allow all the London hospitals to utilize the emanations which could be collected from it at the price of their production. The Middlesex Hospital is the only one of the general London hospitals which contains special wards for the treatment of cancer and a special laboratory for its investigation. It has recently been compelled to withdraw from its capital $5,000 for the purchase of radium. Sir Alfred Pearce Gould, surgeon to the hospital, pointed out the necessity for care in inferring that a case of cancer had been cured by radium, for the disease sometimes underwent spontaneous cure. Recently a man had been discharged from the hospital in robust health although he had been ill for two years with cancer which was pronounced uncurable. Without radium or any specific treatment or operation he recovered. In some cases they had the most striking results; one application of a tube of radium had been followed by rapid disappearance of malignant growth. On the other hand, similar growths had been treated in the same way with no improvement. He had also known half of an extensive area of the disease quickly removed by radium while the other half was entirely unaffected. In some cases burns occurred very rapidly. It would not be accurate to say that radium was a cure for cancer in the same way that drugs were specifics for some diseases. So far as they knew there was no hope that radium would be able to deal with cases in which cancer had diffused itself among the internal organs, but so long as the disease was localized the results were sufficient to say that radium was a more hopeful remedy than anything except operations.

### The Leprosy Problem in the British Empire

Dr. H. Bayon, research bacteriologist to the union government of South Africa, has delivered a lecture with the object of having the government institute a system of registration and segregation of lepers. He said that at present there were from twenty-five to fifty lepers in England, and the simple precautions taken by these unfortunates was sufficient to prevent contagion. In India, on the other hand, there had been an increase of lepers from 100,000 to 110,000. In South Africa the increase was more marked. In Basutoland the principal medical officer counted 300 lepers twenty-five years ago. Last year they numbered from 800 to 900. He submitted that only by segregation could the disease be coped with. Sir Malcolm Morris said that the lepers in London were hunted from one lodging-house to another. Their pitiable condition had caused some benevolent persons to attempt to provide some small institution in which they could be segregated and cared for, but it was necessary to proceed with care because if it became known that a comfortable home was provided for lepers in London they would be attracted here from other countries.

## BERLIN LETTER

*(From Our Regular Correspondent)*

Berlin, Nov. 23, 1913.

### *Personal*

On the occasion of his transfer from Greifswald to Berlin, Professor Loeffler was elected an honorary citizen of the city of Greifswald.

### The Struggle between the Insurance Societies and Physicians

The development of this struggle is going on in the form decided on by the Aerztetag. The present contracts are not being renewed, so that a great number of the Krankenkassen have no longer any physicians under contract to attend their policy-holders. It is reported from various sources that an attempt is being made to resume negotiations for a new agreement between the two parties, but it is scarcely to be assumed that our highest imperial authority will take this step.

### Foundation of an International Society for Sex Investigation

An international society for sex investigation was founded in Berlin November 16, the Internationale Gesellschaft für Sexualforschung. The organizations which are active at present in the field of sexual investigation are chiefly concerned with practical and humanitarian purposes, such as hygienic, educational and legal, social and moral reform. The new society is to devote itself to a purely scientific investigation of sexual problems. For this reason the man at the head of the society is not a physician, but Prof. J. Wolff, who is professor of economics at the technical high school in Charlottenburg (*Lehrender Nationalökonom*). It is also a notable fact that a professor of theology in the Berlin University belongs to the executive committee. In the meeting for organization he emphasized the fact that he hoped for advantages from the new society in three fields, psychology, economics and history.

### Statistics in Regard to Venereal Disease in Germany

The association of German statisticians has determined to secure information with reference to the number of venereal patients at present under medical treatment. As experience has shown and as every practitioner knows, such an investigation will not give the entire number of patients, but the knowledge obtained from the large number of cases available will be of value. A committee appointed by the association in conjunction with the executive committee of the German association for combating venereal diseases has elaborated a plan by which it is to be determined how many persons with venereal disease were under medical treatment in the period from November 20 to December 20, 1913, inclusive. This is determined by including in a table the number of patients visiting the office in this time in such a manner that each patient is reckoned only once. Only chancroid, gonorrhea and syphilis with their consequences are reckoned among venereal diseases. All non-venereal genital affections, such as acuminate condyloma, non-gonorrheal urethritis, herpes genitalis, etc., are not included. In view of the extraordinary importance of tabes and paralysis, separate columns are provided for these with a distinction between old cases and those treated for the first time. The cases treated in the public hospitals are collected directly by the statistical bureau.

### Public Care of the Sick in Berlin for 1912

There were treated in the public municipal hospitals 60,578 persons, which is nearly 2,300 fewer than in the previous year. On the average there were 4,165 patients in the hospitals daily, which is on the average nearly 200 fewer per day than in the previous year. The six hospitals occasioned an expense of $1, 837, 500 (7,350,100 marks) with only $19,629 (78,517 marks) receipts, so that the entire remainder of over $1,800,000 (7,250,000 marks) is to be reckoned as expense. To this must be added the interest on the municipal capital involved, so that the total expense reaches $2,187,048 (8,748,193 marks). The average daily expense for each patient is 98 cents (3.93 marks), as compared with 91 cents (3.66 marks) in the previous year. The actual cost for each patient including the interest on the capital has risen from $1.33 (5.32 marks) daily to $1.43 (5.72 marks), a not inconsiderable increase.

### German Universities in 1913

The number of students matriculated in the universities in the German empire, which has doubled since 1896, has risen further during the last summer. As compared with the previous year, the increase is 7,851, and compared with the summer semester of 1903 is about 24,000. The increase during the last ten years is as great as the entire attendance at the German universities thirty years ago. The annual increase for the last year is somewhat smaller than the previous year, so that it may be assumed that the high point of the increase has been passed, which in view of the overfilling of many learned professions may be regarded as desirable. If to the number of matriculated students, the number of those admitted to the lectures is added (3,079 men and 1,027 women) there are at present attending the German universities 64,462 persons (56,910 men and 3,436 women as compared with 56,602 men and 2,959 women in the previous year). As to the attendance of the different departments, theology showed a marked increase with 3,882 students as compared with 3,338 in the previous year, but the principal increase is seen in the department of medicine, to which university students have given the preference for some years. The medical departments have 14,750 students as compared with 13,409 in the previous year and 8,282 five years ago. The next largest increase is in economics and agriculture. Dentistry decreased as a result of higher entrance requirements and longer time of study from 789 to 655, and law from 11,087 to 10,396, and finally students of philosophy from 16,644 to 15,471.

## BUDAPEST LETTER

*(From Our Occasional Correspondent)*

Budapest, Nov. 29, 1913.

### Preventive Inoculations against Typhoid

The chief medical officer of the county of Zemplen asked the minister of public hygiene (also minister of internal affairs) to provide his county with free vaccine in order that those who come in contact with typhoid patients (as nurses and persons engaged in such occupations as earth-working and privy-cleaning) might be vaccinated. At present the chief medical officer will refrain from making vaccination obligatory; but thinks that the state ought to provide free vaccine, which should be prepared in the bacteriologic laboratory of the university. The minister accepted the proposal with great pleasure, and steps were taken immediately to prepare sufficient vaccine in the ministerial laboratory to meet the requests of any counties for vaccine.

### Lack of Cadavers for Dissection in the Anatomic Institutions

A new resolution has been offered at the workmen's insurance office, according to which any member of the sick-clubs who dies without relatives shall be buried by the respective club. As the number of members in Budapest amounts to about 450,000 (out of a population of 900,000), the new rule threatens medical teaching with a cadaver famine, the more so, as the Chevra Kadisha, a Jewish charitable society, provides funerals for all Jewish subjects whose funeral is not attended to by relatives. Considering that the number of medical students amounts to 2,800 in the Budapest University, while the number of cadavers at the disposal of the anatomic institutions had amounted to only 500 a year, it could justly be feared that the successful teaching of anatomy, operative surgery, etc., would be endangered should the resolution of the workmen's insurance office come into force. To prevent this Anton Genersich asked the minister of public instruction to frame a new bill providing that all cadavers not claimed by relatives may be used for purposes of instruction.

### Eclampsia an Anaphylactic Disease

Dr. Oscar Vertes, assistant of the obstetric clinic of the Kolozsvar University (Hungary) has carried out extensive investigations in the bacteriologic laboratory of the Friedrichshain General Hospital (Berlin) as to the pathogenesis of eclampsia. He sums up the results of his investigations as follows: The pregnant organism is on account of the absorbed villous element (proved by Schmorl) in an anaphylactic state. That the chorionic villi which contain both racial (*arteigen*) and individual (*körpereigen*) albumins, are actually capable of producing eclampsia, has been clearly demonstrated in his experiments. Certain similarities have beeen shown between anaphylactic manifestations and the symptoms of eclampsia. The experimental animals which died have similar organic changes to those of persons dying with eclampsia. The albuminuria also strengthens the assumption that eclampsia is a manifestation of anaphylaxis.

# Marriages

Alexander Contee Thompson, M.D., Greeley, Colo., to Miss Mabel Chesley Berry of Washington, D. C., at Greeley, November 26.

Jesse Lee Hagadorn, M.D., to Miss Phyllis Ivy Maughan, both of Los Angeles, at San Bernardino, Cal., December 1.

Asher Reid McMahon, M.D., Memphis, Tenn., to Miss Geraldine Sembower of Bloomington, Ind., December 6.

James Albert Honeig, M.D., Cambridge, Mass., to Miss Florence Imogene Graham, at Boston, December 6.

Earle Edward Tilton, M.D., Boston, to Miss Mary Christie Stephenson of Port Deposit, Md., December 3.

Edgar Dale Downing, M.D., San Francisco, to Miss Marjorie Fraser Cole of Fallon, Nev., December 1.

Nathaniel A. Thompson, M.D., Denver, to Miss Isabel McKenzie of Boulder, Colo., November 28.

Charles Henry Smith, M.D., Weston, Ore., to Miss Zona M. Sapp of Portland, Ore., November 26.

Henry F. Mikel, M.D., Columbia, Mo., to Mrs. Lida M. Ashton of Peabody, Kan., December 5.

James Albert Corscaden, M.D., to Miss Julia Thomas, both of New York City, December 16.

Nelle Malvina Cole, M.D., and George Owen Reed, both of Michigan City, Ind., November 29.

Warren J. Miller, M.D., to Miss Ina C. Bowman, both of Philadelphia, December 4.

Charles M. Raymond, M.D., Edgewood, R.I., to Mrs. A. C. Newell, November 8.

# Deaths

**William Henry Wishard, M.D.,** one of the oldest, most honored and best beloved practitioners of Indiana, died at his home in Indianapolis, December 9, aged 97. He graduated in medicine in the Indiana Medical College, La Porte, in 1849 and was given the ad eundem degree of M.D. by the Medical College of Indiana, Indianapolis, in 1877. He was one of the founders of the Indiana State Medical Society in 1849 and was the last survivor of its charter members. During the Civil War he served as surgeon of the 59th and 83d Indiana Volunteer Infantry. He was for many years a member of the American Medical Association, served as president of the Indiana State Medical Association in 1889 and as president of the Indianapolis Medical Society in 1891. It is said to have been through Dr. Wishard's efforts that President Lincoln issued the first order for the removal of soldiers, disabled by illness or wounds, from the seat of war to their Northern homes. He continued in active practice in Indianapolis until seven years ago and up to within a few months he attended meetings of the local medical society, where he was reverenced as a fine specimen of the old school doctor. The death of Dr. Wishard removes a stalwart pioneer in medicine of the Middlewest, a gentleman of the old school, a practitioner who stood for the highest ideals, and a friend always loyal and true. The Indianapolis Medical Society at a special meeting, December 11, adopted suitable resolutions regarding the death of Dr. Wishard.

**John Green, M.D.** Harvard Medical School, Boston, 1866; LL.D. (honorary) Washington University, 1905; University of Missouri, 1906; a member of the American Ophthalmological Society, and American Otological Society; ophthalmic surgeon to St. Luke's Hospital, St. Louis; professor of ophthalmology in the Medical Department of Washington University since 1886, and at the time of his death professor emeritus; a pioneer oculist of the Southwest; surgeon of volunteers during the Civil War; one of the founders of the American Ophthalmological Society, Harvard Club of St. Louis, St. Louis Archeological Society and St. Louis Academy of Science; died at his home in St. Louis, December 7, from pneumonia, aged 78.

**Archibald Dixon, Jr., M.D.** Bellevue Hospital Medical College, 1891; of El Paso, Tex.; vice-president of the Kentucky State Medical Association, health officer and formerly city physician of Henderson, Ky.; acting assistant surgeon U. S. Army; a specialist on diseases of the lungs; died at his home, October 31, aged 44.

**Frank Le Moyne, M.D.** University of Pennsylvania, Philadelphia, 1863; a member of the Medical Society of the State of Pennsylvania; brigade surgeon during the Civil War and brevetted lieutenant-colonel for conspicuous gallantry in action; once president of the Allegheny County Medical Society; chairman of the Pittsburgh Water Commission; a trustee of the Elizabeth Steel Magee Hospital; one of the founders of the Pittsburgh Hospital for Children and surgeon to that institution and the Western Pennsylvania Hospital; died at his home in Pittsburgh, December 1, aged 74.

**Jerome Dwelly, M.D.** Harvard Medical School, 1847; a member of the Massachusetts Medical Society; a practitioner of Fall River for more than sixty years; once president of the Bristol South District Medical Society; one of the witnesses of the original demonstration of ether anesthesia and the first to administer it in his own community; first city physician of Fall River; medical examiner of Bristol County for fourteen years; one of the finest types of the old-time practitioner; died at his home in Fall River, December 4, aged 90.

**Rockwood Sager, M.D.** Rush Medical College, 1879; a member of the Illinois State Medical Society; for thirty-four years a practitioner of Rockford; died at his home in that city, December 2, from brain tumor, aged 57. At a meeting of the Winnebago County Medical Society December 4, resolutions were unanimously adopted expressing regret at the death of Dr. Sager and sympathy for his family.

**Harry M. Hayes, M.D.** Rush Medical College, 1894; a Fellow of the American Medical Association, and President of the Peoria City Medical Society; formerly commissioner of health in Peoria; died in the Proctor Hospital in that city, December 2, from typhoid fever, aged 42. At a meeting of the Peoria City Medical Society, December 6, resolutions of regret and sympathy were unanimously adopted.

**George Henderson, M.D.** Howard University, Washington, D. C., 1885; a member of the Medical Association of the District of Columbia; formerly a member of the Association of Military Surgeons of the United States; a veteran of the Civil War; for twenty-three years Surgeon-General of the National Guard of the District of Columbia; died at his home in Washington, November 27, aged 70.

**Warren Oscar Plympton, M.D.** College of Physicians and Surgeons, New York City, 1888; formerly professor of surgery in the New York Postgraduate Medical School; attending surgeon to the Daisy Field Hospital, Englewood, N. J., and consulting surgeon to the Mary Immaculate Hospital, Jamaica, L. I., and the Tarrytown Hospital; died at his home in Westport, Conn., November 19, aged 55.

**Nathaniel Heath Street, M.D.** University of Virginia, Charlotteville, 1880; New York University, New York City, 1881; a member of the Medical Society of the State of North Carolina; died at his home in New Bern, December 1, from the effects of a gunshot wound of the brain, self-inflicted, it is believed with suicidal intent, while suffering from melancholia due to ill health, aged 56.

**John Todd, M.D.** Pennsylvania Medical College, Gettysburg, 1857; for fifty-six years a practitioner of Montgomery County, Pa.; for several years a burgess of Pottstown, and for nine years a member of the town council; president of the medical staff of Pottstown Hospital since the establishment of the institution; died at his home, October 27, from senile debility, aged 83.

**Henry J. Evans, M.D.** Hahnemann Medical College, Philadelphia, 1881; president of the Maryland State Homeopathic Society in 1899 and president of Maryland State Board of Medical Examiners in 1888; consulting physician to St. Luke's Hospital; formerly of Baltimore; died at his summer home in Hollidaysburg, Pa., November 30, from pernicious anemia, aged 58.

**Frederick Ogden Marsh, M.D.** Miami Medical College, Cincinnati, 1884; professor of chemistry and toxicology in his alma mater; of Cincinnati; who was committed to Longview Hospital, October 7, suffering from melancholia; died in that institution, November 24, from the effects of wounds believed to have been self-inflicted with suicidal intent, aged 54.

**Hugh Spencer Williams, M.D.** Northwestern University Medical School, 1894; LL.D., D.D., prominent as a clergyman of the Cumberland Presbyterian Church; died at his home in Memphis, Tenn., December 3, from nephritis, aged 68.

**William Hutchinson Merrill, M.D.** College of Physicians and Surgeons, New York City, 1887; formerly a practitioner of Jeckyl Island, Ga., and later of Pepperell, Mass.; died at his home in the latter city, December 2, aged 53.

**Isaiah Carter Turner, M.D.** Meharry Medical College, Nashville, Tenn., 1885; a well-known colored practitioner of Dayton, Ohio, and a member of the National Guard, who served throughout the floods in April of this year; died at the home of his father in Owensboro, Ky., December 1, aged 39.

**William Ernest Miller, M.D.** College of Physicians and Surgeons, Baltimore, 1892; a Fellow of the American Medical Association; a well-known practitioner of Northwestern Baltimore; died in the Franklin Square Hospital in that city, November 23, from cerebral hemorrhage, aged 43.

**Adolphus Woodville Dail, M.D.** Tennessee Medical College, Knoxville, 1891; a Fellow of the American Medical Association; for eleven years a practitioner of Cement, Okla.; died in the Washita Valley Hospital, Chickasha, Okla., November 20, from tubercular peritonitis, aged 44.

**Charles Edward Wachenschwanz, M.D.** University of Jena, 1850; formerly demonstrator of anatomy in Starling Medical College, Columbus, Ohio; a surgeon of volunteers during the Civil War; died at his home in Chillicothe, Ohio, November 7, from senile debility, aged 83.

**Richard Cranch Greenleaf, M.D.** Harvard Medical School, 1870; a trustee of the Lenox Library and Lenox Academy and town assessor for several years; a member of the Massachusetts Medical Society; died at Lawrence, L. I., December 3, from heart disease, aged 68.

**Evan S. Weisiger, M.D.** Pennsylvania University, Lexington, Ky., 1852; surgeon in the Confederate service during the Civil War; for fifteen years state quarantine officer at the mouth of the Brazos River, Tex.; died at his home in Brazoria, Tex., October 8, aged 83.

**Thomas J. McClosky, M.D.** St. Louis College of Physicians and Surgeons, 1889; a member of the Wisconsin State Medical Society; formerly a practitioner of Prairie du Chien and Beloit; died at the home of his sister in Dubuque, Iowa, November 28, aged 53.

**Horace H. Tinker, M.D.** New York Homeopathical Medical College, New York City, 1875; of New York City; died at his summer home in New London, Conn., November 20, from the effects of poison believed to have been self-administered with suicidal intent, aged 61.

**Charles De Witt Rawson, Jr., M.D.** Drake University, Des Moines, Ia., 1905; of Otley, Ia.; who was seriously injured in an automobile accident near Otley, November 13, died at his home in that city from the effects of his injuries, November 19, aged 31.

**James Lawrence Turner, M.D.** University of Georgetown, Washington, D. C., 1864; a veteran of the Civil War and for many years a practitioner of New York City; died at his home in Corona, Long Island, November 16, from pneumonia, aged 75.

**Thomas Edwin Nott, Jr., M.D.** Tulane University, New Orleans, 1885; formerly a practitioner of Spartanburg, S. C., but recently a resident of Brownsville, Tex.; died in that place, November 24, from tetanus due to a needle wound, aged 48.

**Allen L. Woode, M.D.** Hygeio-Therapeutic College of New York City, 1863; a resident of Flatbush, L. I.; for thirty-five years president of the Clinton Street Baths, Brooklyn; died in the Paul Kimball Hospital, Lakewood, N. J., October 25, aged 73.

**Charles Young Moore, M.D.** University of Toronto, Ont., 1871, and silver medallist of his year; for more than forty-five years a practitioner of Brampton, Ont., and medical officer of health of that place; died at his home, September 11, aged 66.

**Anita E. Tyng, M.D.** Woman's Medical College, Philadelphia, 1864; at one time a medical missionary in the Orient and formerly a member of the Rhode Island Medical Society; died at her home in Berkeley, Cal., October 16, aged 73.

**H. G. Patterson** (license, Kansas, 1901); a veteran of the Civil War; for thirty years a practitioner of northwestern Kansas; medical director of the Kansas State G. A. R. in 1907; died at his home in Rexford, November 29.

**Dr. Charles Morton Clifford, M.D.** Miami Medical College, Cincinnati, 1893; a Fellow of the American Medical Association; formerly a practitioner of Cynthiana, Ky.; died at his home in Le Roy, Ill., November 24, aged 46.

**Alexander S. Cornell, M.D.** Detroit College of Medicine, 1894; was instantly killed December 2, at his home in Copemish, Mich., by his own automobile, which he was cranking without having put the machine out of gear.

**Woodson B. Fearing**, M.D. University of Maryland, Baltimore, 1881; a member of the Medical Society of the State of North Carolina; of Manteo; died in the Sarah Leigh Hospital, Norfolk, Va., December 2, aged 54.

**Robert Lyon Sanderson**, M.D. Cleveland University of Medicine and Surgery, 1857; for many years medical officer of health for the township of Yarmouth, Ont.; died at his home in Sparta, Ont., September 23, aged 81.

**John Gould**, M.D. University of Michigan, Ann Arbor, 1890; for four years assistant superintendent of the Yankton (S. Dak.) State Hospital for the Insane; died at his home in Denver, Col., November 24, aged 55.

**W. L. Simmons**, M.D. Graffenburg Institute, Dadeville, Ala., 1858; for more than forty years a practitioner of Weatherford, Tex.; died in a sanatorium at Fort Worth, November 19, from senile debility, aged 81.

**John J. Baker**, M.D. Physio-Medical College of Indiana, Indianapolis, 1875; formerly of Westfield, Ind., and Indianapolis; died at the home of his daughter in Peru, Ind., October 29, aged 62.

**Meredith Taylor** (license, Missouri, 1883); formerly circuit court judge of Jasper County; died at the Odd Fellows' Home, Liberty, Mo., September 24, from cerebral hemorrhage, aged 63.

**George Washington Wise**, M.D. Medical College of Georgia, Augusta, 1861; for many years a practitioner of Trenton, S. C.; died in the Columbia, S. C. City Hospital, November 4, aged 74.

**Ellsworth Henry Way**, M.D. Cleveland University of Medicine and Surgery, 1874; founder of the Riverside (Cal.) Hospital; died at his home in Riverside, October 21, aged 52.

**Salmon Stebbens Douglas**, M.D. Chicago Homeopathic College, 1892; coroner of Delaware County, Iowa; died at his home in Earlville, November 28, of pneumonia, aged 45.

**Thomas Henry Ullyot**, M.D. University of Southern California, Los Angeles, 1908; died at his home in Pomona, Cal., November 7, from ptomain poisoning, aged 32.

**William M. Edwards**, M.D. University of Alabama, Mobile, 1880; died at his home in St. Elmo, Mobile County, November 26, from cerebral hemorrhage, aged 59.

**Alfred Layman**, M.D. Hahnemann Medical College, Philadelphia, 1882; died at his home in Philadelphia, December 6, from carcinoma of the stomach, aged 70.

**Fleming B. Todd** (license, Missouri, 1883); for more than forty years a practitioner of North Central Missouri; died at his home in Madison, September 18.

**James H. Willis** (license, fifty years' practice, Kentucky, 1895); a veteran of the Mexican War; died at his home in Lawrenceburg, November 10, aged 90.

**Henry C. Williams** (license, Michigan, 1900); for more than fifty years a practitioner of Morenci, Mich.; died at his home in that village, November 3, aged 79.

**Leandre Coyteaux Prevost**, M.D. Ecole de Médécine et de Chirurgie, Montreal, 1874; of Ottawa, Ont.; died at Saranac Lake, N. Y., November 6, aged 63.

**Joseph G. Williamson**, M.D. Bennett Medical College, Chicago, 1882; formerly of LaGrange, Ill.; died at his home in Montague, Mich., November 5.

**Richard David Hailey**, M.D. University of Louisville, Ky., 1909; died at his home in Olive Hill, Tenn., August 6, from pernicious malarial fever, aged 38.

**John Oscar Stevens** (license, Texas, 1898); of Hobbs; was shot and instantly killed while driving through Camp Springs, Tex., November 13, aged 46.

**Clarence E. Frey**, M.D. Hospital College of Medicine, Louisville, 1906; died at his home in Louisville, November 30, from pneumonia, aged 32.

**Robert Charles Meyers**, M.D. University of California, San Francisco, 1880; formerly of San Francisco; died in Los Altos, Cal., November 23.

**Julius L. Schauer**, M.D. College of Physicians and Surgeons, Baltimore, 1891; formerly of Milwaukee; died in Chula Vista, Cal., August 26, aged 48.

**Gerald Waddell**, M.D. McGill University, Montreal, 1907; of Montreal; died in Chatham, Ont., July 13, from carcinoma of the stomach, aged 29.

**Calvin Lutz**, M.D. Victoria College, Coburg, Ont., 1868; died at his home in Gananoque, Ont., September 14, aged 62.

# The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

## THE JIREH DIABETIC FOOD COMPANY

### The Company Rises to Explain in a Brief Note of One Thousand Words

Exploiters of fraudulent and dangerous pharmaceutical products have no love for The Journal. When such products are exposed in these pages, their manufacturers seldom reply to the criticisms except through indirect channels. Then the replies are frequently replete with billingsgate and denunciation of The Journal and its editor, the Association and the medical profession generally.

We have, at different times, had to call the attention of the public and the medical profession to the fraudulence and dangers of some of the products of the Jireh Diabetic Food Company. We have shown that the Jireh company lied boldly and directly so long as it could do so without getting into the courts, and that it lies inferentially still; we have shown that Jireh flour had practically as much carbohydrate as ordinary flour; we have shown that, probably to escape prosecution under the Food and Drugs Act, the Jireh concern has coined the word "diatetic" and substituted it for the word "diabetic," which used to appear in its advertisements; we have shown that the claim made for the Jireh products that they are "starch-changed" was a false one, and that the company has modified this to "starch-treated," presumably to avoid being haled into the courts under the "pure food law"; we have shown, in short, the unreliability both of the Jireh concern and of its products.

Two or three weeks ago a New York physician wrote to The Journal for information regarding the Jireh products. We sent him such matter as had been published on the subject, and he showed this material to a patient who was using the Jireh products. The patient, in turn, expressed her opinion of the product to the retailer from whom she had been purchasing it. A day or two later she received a letter from the Jireh Diabetic Food Company, which, in spite of its length and discursiveness, we publish in full, so that physicians may know just what this company thinks of them. The letter, which is dated Nov. 20, 1913, really belongs in the "Knocks and Boosts" department, but its length prevents its use there. Here it is:

> "We learned through Mess. Cushman Co. that you are a constant user of Jireh Foods for some time past, and that recently a certain derogatory statement was brought to your attention relative to our product. We feel an explanation is due you for two reasons.
>
> "First, because we want you to continue using Jireh Foods and thus receive the benefits of the same; and second, that the remarks called to your attention are not only libelous, but are in no way pertinent enough to detract from the value of our product. In the first place, we want to state that the particular journal in question has been endeavoring to injure our business for some time past and that we are not the only descent [*sic*] manufacturers of foods that are suffering in this way at the hands of the editors of this particular magazine. Since you are interested in the Jireh Foods, you may be more interested to learn why this particular magazine is so anxious to injure our reputation. The reason is very obvious if you will take into account the fact that this magazine is the official journal of the medical association of this country which is known as the backer of the medical trust. It is very clear to you, no doubt, that there are some physicians, particularly those that are associated with the magazine, who are anxious to stamp out of existance [*sic*] such concerns that offer a bona fide product, a meritorious product which actually produces the required results without the aid of medicine.
>
> "For the particular maladies for which we offer our foods, we have been very successful, consequently the antagonism on the part of this particular journal is the logical thing. In addition to this, however, and perhaps more important to us, is the fact that the editors of this magazine have made it known to us that they will not approve of our product until such time that

we care to be dominated by the moving influence of the magazine in question. They want us to supply them with the private formula which we use for manufacturing our foods and to enlighten them and show them the various processes applied to our products to produce the required results. As a bona fide and ethical business house, we absolutely and unqualifiedly refuse to comply with this wish, and will always refuse to do so, no matter how often they may attack us. We stand strictly upon principle in this matter and propose to run our business in our own way, and will not, under any circumstances, allow a magazine or anybody else dictate to us under what conditions we are allowed to do our business.

"The remarks which they make would perhaps hurt us some if they emanated from a source that was qualified to judge the merits of our food. The absurd side of the issue, and perhaps the comical side of it, is the fact that the honorable gentlemen who assume to condemn a product, know less about the disease for which the product is offered, and much less about diet and foods than the average layman. Consequently, we consider it simply absurd to allow them to step into our business and dictate policy to us. This is the gist [*sic*] of the discontent that prevails between the magazine editors and ourselves, and as long as we refuse to comply with their wish, we certainly cannot expect them to speak well of us. It has become a notorious fact in the medical profession that their criticisms are almost valueless, inasmuch as they stop at nothing in order to create sensationalism, and have attacked not only ourselves, but every bona fide manufacturer of foods and drugs in this country who has refused to fall in line with them.

"This explanation, we trust, will appeal to your good judgment and will convince you of what is said about us is untrue. Furthermore, our business has grown to colossal proportions, notwithstanding their endeavors to crush us. We call your attention to a most peculiar fact: that is, that they make no comment whatsoever as to the product and its therapeutic value in the treatment of diabetes. You notice they make an awful play on our literature, which was changed merely to suit conditions in business. We also wish to call your attention to another peculiar fact, and that is that a great majority of the physicians who are in with this magazine readily recommended our foods, and we also believe that your physician, after reading this letter, will feel the same way as most physicians do in relation to our foods. We believe that your physician is perfectly willing to be convinced that our foods are as represented to be, and the very best clinical evidence as this is the effect our foods have had upon you. Finally, if the foods are palatable and wholesome and have alleviated the annoying symptoms of Diabetes, then why should you be guided by the opinions of demagogues and yellow journalists?

"You may be pleased to learn that our foods have received the attention of Dr. Wiley, the well-known chemist and food scientist of this country, and we have now in our possession his reports showing the very high standard of our foods. This, in our opinion, is of more consequence than all the harangue which those venerable gentlemen of the magazine may indulge in.

"We want to convince you without an atom of doubt that we are honest and bona fide in everything we say, and we extend to you a hearty invitation to call at the first opportunity and shall be glad to tell you anything you may wish to know. Thus awaiting the pleasure of this visit, we beg to remain

"Yours very truly, JIREH DIABETIC FOOD CO."

We learn from this letter that THE JOURNAL'S "remarks" on the Jireh product are "libelous." We have made them many times and for several years past; if libelous, the manufacturer has excellent grounds for damages. We learn, too, that our remarks "are in no way pertinent enough to detract from the value" of the Jireh products. Why, then, take any notice of them? We learn, moreover, for the hundred-and-first time, that THE JOURNAL is the official organ of the "medical trust," and we are told that "there are some physicians" that are opposed to the Jireh Foods because these products cure diabetes without the use of medicine! THE JOURNAL, so the company says, wants the Jireh Diabetic Food Company to supply its "private formula" and to show the "various processes" by which the Jireh products are made. Such statements indicate that the Jireh Diabetic Food Company does not confine its mendacity to the mere advertising of its product, where the necessity for lying is naturally great.

The ambiguous remarks regarding Dr. Wiley are evidently intended to convey the idea that the doctor approves of the Jireh products. Dr. Wiley was sent a copy of the Jireh letter and his attention directed to the statements appearing therein regarding himself. He replied:

"In regard to the Jireh products and their claims that our reports show the very high standing of their foods, I would say that I consider such a claim entirely false. . . . We did examine five or six products in our own laboratory, however, and found them to be of very fair composition per se, but *not of a composition that afforded any legitimate basis for their claims. We entirely disapproved* . . . *three of the products making special claim as to their fitness for diabetics.* [Italics ours.—ED.] These were the Wheat Nuts, the Jireh Flour and the Patent Barley. Two of the other products were passed with a non-committal rating, which means that they are not actually disapproved, but the star marking is not accorded. These products were the dietetic Rusks and the Macaroni. For the latter especially no specific claims seem to be made. We called attention, however, to the generally objectionable juggling of terms indulged in by this company. . . ."

The Jireh concern says that in spite of the efforts of THE JOURNAL to "crush" it, "our business has grown to colossal proportions." Of this the New York physician who sends us the letter says: "Their 'colossal proportions' must have received a slight jar or they would not have taken time to write such a letter."

The following medical journals carry the advertisements of the dangerous and fraudulent Jireh products:

*Dietetic and Hygienic Gazette*
*Medical Times*
*Pediatrics*
*Medical Herald*

## DOWD'S PHOSPHATOMETER

Dowd's Phosphatometer, according to its inventor, is a device "for taking the phosphatic index or pulse of the nervous system." Its originator, J. Henry Dowd, M.D., Buffalo, N. Y., writes enthusiastically of his instrument:

> "Physicians who use the Phosphatometer are sending 50 per cent. less patients away for consultation, getting 75 per cent. better results at home, because the Phosphatometer tells the cause and what to do, and the Comp. Phosphorus Tonic gives results in 80 per cent. of all conditions of illness."

The "Comp. Phosphorus Tonic" referred to in the above quotation is a sideline of Dr. Dowd's, put out by the Richardson Company of Buffalo. The stationery of the Richardson Company gives its address as 334 Franklin Street, but directs that all communications be addressed to 40 North Pearl Street, which is the private address of J. Henry Dowd. According to the Buffalo directories, 334 Franklin Street is the drug store of Arthur E. Reimann.

To those who read the Dowd "literature," the Phosphatometer will appear to be either one of the wonders of the age or an unscientific absurdity. To the thinking man it will be the latter. It pretends to determine the amount of phosphates in the system. This is accomplished—alleged—by taking the second urine passed in the morning and mixing a portion of it in the instrument with a solution which is the well-known magnesia mixture. The height to which the crystals settle in ten minutes determines, according to Dowd, the amount of phosphates! Was ever a test devised that violated more of the first principles of quantitative chemical analysis? If so, we never heard of it. Dowd's system does not require any determination of the amount of urine passed in twenty-four hours or even of the amount passed at the second micturition in the morning.

If a patient whose urine was being "tested" by the Dowd method, should drink two cups of coffee for breakfast instead of one, his urine might be so dilute that the phosphates would fall below the "normal" mark. Dowd says that his Phosphatometer "takes the pulse of the nervous system." What about the patient who eats several eggs or consumes a sweetbread or other nuclein-containing articles of diet? The increased amount of phosphates in such a diet might easily lead to an apparent excess in the urine. Every physician, nay, every sophomore medical student, knows that the amount and kind of food ingested governs almost entirely the amount of phosphates excreted in the urine.

What actually does "Dowd's Phosphatometer," when used according to instructions, show? It shows the *presence* of phosphates in the urine; it permits a guess—with not the slightest claim to accuracy—as to the amount in the specimen tested; it gives no possible clue to the normal or abnormal relation of the phosphates in the urine or as to whether the source of the crystals precipitated is the nerve tissue or the food. Yet here are some of the claims made for it:

> "The Phosphatometer shows nervous metabolism the same as the ureometer shows muscular; the former errs in about 3 per cent.; the latter in 40 per cent."
>
> "The Phosphatometer shows the amount of nerve food being used and present in the nerve cells."
>
> "Over 50 per cent. of pain and human suffering is due to the nerves crying for food; the Phosphatometer will show the true cause in ten minutes."
>
> "The Index not only tells the present condition, but foretells the future, thus preventing serious complications which might arise."
>
> "The Phosphatometer measures the amount of phosphorus in the system."
>
> "The Dowd Phosphatometer not only takes blood-pressure, it tells how to regulate it."
>
> "The Phosphatometer measures the amount of phosphorus in the nerve cells; it is as positive in nerve troubles as the x-ray in fractures."

These claims are essentially false. As a matter of fact, a simple examination of the urine for phosphates cannot tell us the condition of the nervous system. This must be evident from the fact that only a portion of the phosphates is excreted in the urine, a very considerable part passing out with the feces. Further, the bulk of the phosphorus excreted comes from the food and only a small portion from the waste of the nervous system. The amount excreted by the urine which comes from torn-down nerve tissue is so small that it is practically impossible to estimate variations in it even by the most careful analytic methods.

In brief, Dowd's "scientific method" is nothing more than unscientific humbug.

### PULMONOL

#### Some Facts from the Inside

The letter that follows was received a few days ago:

"*To the Editor.*—I congratulate you on the article which appears in THE JOURNAL, Nov. 29, 1913, on Pulmonol.

"I have been fiscal agent for several companies, and some three years ago I was persuaded to take up the floating of Pulmonol. I did this after investigating and coming to the conclusion that the medicine was all that was claimed for it. I had not been in the business very long, however, before I found out that I had been deceived.

"The first case you mention, which was supposed to be so wonderful that the Committee on Tuberculosis was asked to investigate, was my first eye opener. Some time after this woman's death her daughter came to the office insisting and then *pleading* that the testimonial be discontinued, but Dr. Payne absolutely refused. Feeling how manifestly unfair it was to give the name of a dead person as a testimonial for the medicine was one of the reasons for my quarrel with the "medical director" and for my getting out of the concern.

"Some months after I left him, he continued to use this testimonial, advertising it considerably in and around New York. I drew the attention of the editor, whom I knew, of one of the newspapers in which the ad. was appearing, and he immediately discontinued it. Riker & Company, under whose name the advertisement appeared, also insisted that Dr. Payne omit this testimonial from his circulars in future.

"Pulmonol is being pushed very much in and around New York, and I think your article ought to be reprinted and spread broadcast and so help those poor people who have been deluded into believing that it really aids them in fighting the disease.

"I do not know whether or not your Journal is published for medical men alone. If not, I wish you would send me three copies, for which I will forward you forty-five cents on hearing from you. I would like to bring the article before Riker & Company, for I know this to be a reputable concern and I do not think they would longer stand behind and push a medicine like this after reading an article so convincing as yours of its fraudulent character.

"RANSON CAYGILL, 82-90 Beaver St., New York City."

The information contained in this letter is interesting and instructive, but that is not the reason we are publishing it. We are bringing it to the attention of our readers because it is typical of letters that come almost daily to this office from laymen who are interested in the work THE JOURNAL is doing in exposing medical frauds on the public. This phase of the propaganda work is encouraging and fruitful of good results. It is in the "ethical proprietary" field that come the greatest discouragements. The "proprietaries" sold to physicians, which THE JOURNAL is exposing, are in every case a disgrace to scientific medicine and in many cases, at least, just as fraudulent as the various "patent medicines." Yet physicians do not exhibit anything like the enthusiasm over exposures of this sort of thing that they and the public show in the case of "patent medicines." This attitude is an unworthy one. Sooner or later the knowledge that the public is gaining regarding "patent medicine" frauds will cause it to focus its attention on the proprietary evil as it affects the medical profession. When that time comes will it be shown that the physicians of the country have cleaned house? If not, the profession will suffer a loss of confidence on the part of the more intelligent portion of the public that will not easily be regained.

## Correspondence

### Method of Sterilizing Rubber Gloves

*To the Editor:*—The method of sterilizing rubber gloves by two tablets (weight not given) of mercuric cyanid in 4 ounces of alcohol and 4 ounces of talc (time not given) is acknowledged by Dr. Ray Ernest Smith (THE JOURNAL, Nov. 15, 1913, p. 1831) to be "theoretically" inefficient; but he says that the gloves "practically surely seem" to be sterile. There are no degrees of sterility of gloves; gloves are either sterile or not sterile and all gloves must be considered contaminated until they are sterile.

Mercuric cyanid is useless as a germicide, as may be seen by any one sufficiently interested to read Harrington's article (*Boston Med. and Surg. Jour.*, Jan. 14, 1904). He tested the cyanid in all strengths and mixtures and found that in a 1:500 solution it had no effect on the staphylococcus after thirty minutes. He concluded that in the strength recommended, 1:1,000, it did not destroy known pus organisms in three hours and that it was an inefficient germicide.

Dr. Smith asserts that hot water and soap followed by alcohol and cyanid are sufficient to sterilize gloves for obstetric work. He states that "some of our famous surgeons" use washing, followed by alcohol, to sterilize their hands. Schumberg (*Arch. f. klin. Chir.*, 1906, lxxix, 1) found that in most cases the hands showed more bacteria than before scrubbing, which he ascribed to the bringing of bacteria to the surface from the gland crypts, and that subsequent bichlorid scrubbing did no good. He found a fat solvent of benefit. Aperlo (*Clin. Chir.*, 1913, xxi, 331) concluded that continued washing with warm water and soap, using a sterile brush, was not sufficient to remove germs from the hands, and that the result was no better if the washing was continued for an hour. How, then, does Dr. Smith expect to rinse his gloves clean with hot water?

Alcohol is a poor germicide. Koch grew spores after 110 hours in alcohol. Goenner grew the streptococcus after fifteen minutes in alcohol, and Senger the *Staphylococcus aureus* after twenty minutes. An evidence of its weak action is the large percentage of alcohol required to preserve various proprietary liquid foods, in which it is used only as an antiseptic and not as a germicide. I have frequently recovered organisms from the previously infected hand after five minutes' immersion in alcohol, and Schumberg states that the reduction of the bacteria is only quantitative and not absolute.

All skin germicides should be fat solvents in order to penetrate the sweat-glands and hair-follicles. Organisms may reside within these and the entrance be blocked with fat, or they may exist within the fat itself. Alcohol is not a good fat solvent; it dissolves the fatty acid, but not the glycerid in which form the fat in the skin always exists. This is one reason why alcohol is not a good skin germicide. The concentration of alcohol is of no importance; it is too weak germicidally to matter whether it is 70 or 95 per cent.

I would repeat my advice that gloves should be boiled in water (fifteen minutes is sufficient) or glycerin or put in the steam sterilizer for thirty minutes at 120 C. (248 F.) with 15 pounds' pressure. The mercuric salts and alcohol are useless for the disinfection of rubber gloves.

Ellice McDonald, M.D., New York.

### The Truth About Ozone

*To the Editor:*—Hardly a month passes without some request coming to this laboratory concerning ozonizers and the uses of ozone for ventilating purposes. It was therefore encouraging to read the recent article of Drs. Jordan and Carlson (The Journal, Sept. 27, 1913, p. 1007) on the properties of ozone, as well as that of Sawyer, Beckwith and Skolfield (*ibid.*, p. 1013), concerning tests on ozone machines. These give the most definite data yet published on the subject. During the past year I have had several opportunities to see installations of these machines in a number of places. Invariably the odor of ozone could be detected only close to the machine. As the odor in very small quantities can be so readily noticed, this means that the gas was not being distributed far from its source. In some places good results were claimed for the machine. It has been my opinion that these results can be fully accounted for by the increased circulation of air in the room caused by the fan in the machine, as you have suggested in a recent editorial (The Journal, Sept. 27, 1913, p. 1045).

One instance of definite results may be of interest. An ozonizer was installed in a room in which it was necessary to exclude even small quantities of dust and dirt on account of the purpose to which the room was put. It was hoped that the ozone would relieve the usual stuffy condition. The irritating effects of the ozone were so great that the workmen refused to stay in the room unless the machine was removed.

It seems as if the positive results obtained by Jordan and Carlson and Sawyer were such that further data are unnecessary, and that we can finally give up the fallacy that ozone is of use in air purification.

John F. Norton, Laboratory of Sanitary Chemistry, Massachusetts Institute of Technology, Boston.

### Stethophone, Not Stethoscope

*To the Editor:*—Hippocrates employed immediate auscultation. Laënnec conceived the idea that mediate auscultation is practicable, and first used a roll of paper between his ear and the patient's chest. Later he constructed the monaural stethoscope, which is still the favorite instrument of many clinicians in Europe.

From the days of Laënnec (1816) up to the present, for the last ninety-seven years, the instrument has been called the stethoscope. The word is of Greek origin. It is compounded of *στῆθος*, breast, chest, and *σκοπέω* inspect, see. The word "stethophone" would be compounded of stethos and the suffix phone, which means sound or voice.

In the days preceding the ophthalmoscope, the auriscope, cystoscope, gastroscope, bronchoscope or the phoneidoscope, and in the days preceding the telephone, graphophone, dictaphone and microphone, the word stethoscope need not perhaps have been criticized; but in the present day I believe it is just as well that our classification be correct. It is clear then, that the name of instruments by the use of which we see, when the proper terminology is used, end in the suffix "scope," while the name of instruments by the use of which we hear, should end in the suffix "phone." In this connection, the phoneidoscope, an instrument to make visible the effect of sound, bears a very instructive name. We may find ourselves reluctant to give up an error which can soon celebrate its centennial, but if a stethophone it is, "why then miscall it?"

Joseph H. Barach, M.D., Pittsburgh, Pa.

## Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

### DRESSING FOR LABORATORY TABLES

*To the Editor:*—Please publish the formula for the dressing for laboratory tables which makes them acid- and stain-proof. This formula appeared in The Journal some time ago but I am unable to locate it.

William H. Deaderick, M.D., Hot Springs, Ark.

Answer.—The formula for the ebonizing preparation said to render laboratory tables resistant to staining or corroding chemical reagents calls for two solutions as follows:

| | |
|---|---|
| Solution A: | |
| Copper sulphate and potassium chlorate, each | 125 gm. |
| Water | 1,000 gm. |
| Boil till salts are dissolved. | |
| Solution B: | |
| Anilin hydrochlorid | 150 gm. |
| Water | 1,000 gm. |
| or: | |
| Anilin | 120 gm. |
| Hydrochloric acid | 180 gm. |
| Water | 1,000 gm. |

Two coats of Solution A are applied while hot, the second as soon as the first has dried. Two coats of Solution B are applied and the wood allowed to dry thoroughly. Next a coat of raw linseed oil is rubbed in by means of a cloth to give a polish. In the treatment with the oil, the deep black color is partially brought out, but this does not uniformly appear until the table has been thoroughly washed with hot soapsuds. This latter treatment removes superfluous chemicals. To keep the table in condition it is said to be necessary only to wash off occasionally with soap and water and then to rub with oil. The cost of both solutions will not be over 50 cents. The amount is sufficient for ten square yards of surface.

### KOWARSKY BLOOD-TEST FOR DIABETES

In The Journal, Nov. 22, 1913, p. 1921, we published through error the Kowarsky test for sugar in the urine instead of the test for differential diagnosis of diabetes. The method of Kowarsky is a modification of that of Bertrand, the principle of which is the reduction of a copper solution by the sugar-containing liquid and solution of the cuprous oxid in an acid solution of ferrous sulphate which causes the separation of an equivalent amount of ferrous oxid, the quantity of which is determined by titration with potassium permanganate.

The technic is substantially as follows: Two flask-shaped tubes graduated with two marks indicating 0.5 and 1 c.c. contents are filled to the lower mark by means of a capillary pipet with a 2 per cent. sodium fluorid solution. Blood carefully drawn from the finger-tip is added to the upper mark, foam being removed by a drop of ether. The mixture is removed to a centrifuge tube with two marks, and the rinsings of the tube added up to the lower mark (5 c.c.). A little powdered sodium tartrate is dissolved in the liquid, 4 c.c. of a dilution of liquor ferri dialysati (1:1) are added. the tube corked, shaken and let stand for five minutes. It is then filled to the mark with liquor ferri dialysati, well shaken and centrifuged for from five to ten minutes. 2 c.c. of a solution containing copper sulphate, 0.8; pure glucose, 0.1, and water, 200, is mixed with 2 c.c. of one containing sodium tartrate, 40; sodium hydroxid, 30, and water, 200. in a small Erlenmeyer flask (of from 30 to 40 c.c. capacity) and exactly 5 c.c. of the clear liquid in the centrifuge added. The mixture is heated to boiling, boiled gently for three minutes and cooled by letting the flask stand in water five minutes. The mixture is filtered through a carefully tested asbestos filter by means of a filter pump. The residue is thoroughly washed, care being taken that the cuprous oxid remains on the superficial layer of the filter. The filter pump is detached, the cork bearing the filter is placed in the Erlenmeyer flask, and the cuprous oxid dissolved through the filter in 3 c.c. of the following solution: ferrous sulphate, 10; sulphuric acid, 40, and water, 200. The filter is washed until filtrate and washings equal not more than 10 or 12 c.c., which are then titrated with a 1:2,000 potassium permanganate solution until a distinct rose color remains.

The results are calculated in the following way: The number of cubic centimeters of permanganate solution used in the titration multiplied by 0.91 gives the amount of copper. The amount of sugar corresponding to the amount of copper is given in the accompanying table:

| Sugar | Copper | Sugar | Copper |
|---|---|---|---|
| 1.0 | 1.95 | 2.3 | 4.45 |
| 1.1 | 2.15 | 2.4 | 4.65 |
| 1.2 | 2.35 | 2.5 | 4.80 |
| 1.3 | 2.55 | 2.6 | 5.00 |
| 1.4 | 2.75 | 2.7 | 5.20 |
| 1.5 | 2.90 | 2.8 | 5.40 |
| 1.6 | 3.10 | 2.9 | 5.60 |
| 1.7 | 3.30 | 3.0 | 5.75 |
| 1.8 | 3.50 | 3.1 | 5.95 |
| 1.9 | 3.70 | 3.2 | 6.15 |
| 2.0 | 3.85 | 3.3 | 6.35 |
| 2.1 | 4.05 | 3.4 | 6.55 |
| 2.2 | 4.25 | 3.5 | 6.70 |

From this amount 1 mg. must be subtracted as being the amount already present in the solution used. The amount obtained by this subtraction corresponds to the amount present in 0.25 c.c. of blood, as only half of the amount of blood taken was used in the titration.

The whole process can be carried out in not more than thirty or forty minutes. Like every other quantitative method, it requires a certain amount of practice. Beginners should first learn to determine the amount of sugar in the solution used. (See *Deutsch. med. Wchnschr.*, Aug. 21, 1913, p. 1635.)

## COMPLEMENT-FIXATION TEST FOR GONORRHEA

*To the Editor:*—1. Is the complement-fixation test for gonorrhea supposed to disappear as a case of gonorrhea, or a complication, progresses toward recovery?

2. Kindly give me a few references covering this point.

O. J. MINK, M.D., Bremerton, Wash.

ANSWER.—1. According to the gonorrhea complement-fixation test, the antibodies can be present for at least two years after infection, but we find no record of a single positive reaction occurring after two years.

2. The following are references for the past two years:

Rockwood, H. L.: Complement-Fixation Test in Gonorrhea, *Cleveland Med. Jour.*, January, 1913; abstr., THE JOURNAL, March 1, 1913, p. 697.

Owen, R. C., and Snure, H.: Complement-Fixation Test in Diagnosis of Gonorrhea, *Jour. Michigan State Med. Soc.*, May, 1913; abstr., THE JOURNAL, May 24, 1913, p. 1666.

Value of the Complement-Fixation Test in Gonorrhea, THE JOURNAL, Queries and Minor Notes, March 23, 1912, p. 881.

Gonorrheal Complement-Fixation Reaction, THE JOURNAL, Society Proceedings, April 27, 1912, p. 1307.

McNeill, A.: Complement-Fixation Test for Gonorrhea, *Arch. Pediat.*, September, 1913.

Lespinasse, V. D., and Wolff, M.: Clinical Value of Gonorrhea Complement-Fixation Test, *Illinois Med. Jour.*, January, 1913.

O'Neil, R. F.: Results of Complement-Fixation Test for Gonorrhea at Massachusetts General Hospital, *Boston Med. and Surg. Jour.*, Oct. 3, 1912.

## URIC ACID TESTS—VALUE OF SODIUM CACODYLATE—PALATABLE ADMINISTRATION OF OLEORESINA ASPIDII—STRENGTH OF PHENOCO—VARIOUS PROPRIETARIES

*To the Editor:*—1. Is there any test other than a complicated quantitative analysis by which a physician can determine whether or not there is an excessive amount of uric acid in the urine?

2. Has Deschien's Syrup of Hemoglobin been accepted for the N. N. R.? Is it an ethical proprietary or a secret formula fraud?

3. What value has sodium cacodylate hypodermically? Is it of any value as a "tonic"—as a hematinic?

4. What is your opinion of Electrargol, Electraurol, Electroplatinol?

5. How can oleoresina aspidii be administered palatably to a child unable to swallow capsules?

6. I have been in the habit of storing tubes of catgut, glass catheters and rubber gloves, also of cooling instruments in phenol 5 per cent., or bichlorid 1:1,000. What strength of "phenoco" should be used for equal effect, or will it not take the place of the others?

M. D. L.

ANSWER.—1. The amount of uric acid can be determined in a convenient way, sufficiently accurate for most clinical purposes, by means of Ruhemann's method with an instrument known as the "uricometer," or by the "purinometer" introduced by Hall. These methods may sometimes be serviceable in practice. The technic is described in recent works on laboratory diagnosis. Usually it will be necessary to know the amount of purin nitrogen that is being ingested, or to place the patient on a purin-free diet before making the estimation.

2. We have no information regarding Deschien's Syrup of Hemoglobin. It is a proprietary product.

3. Sodium cacodylate has the effects of preparations of arsenic in general, and might be used in the same way as other arsenic compounds as a tonic and hematinic. (See N. N. R., 1913, p. 239.)

4. Electrargol, Electraurol and Electroplatinol are preparations of colloidal metals. The claims made for them appear to be very optimistic.

5. Oleoresina aspidii may be given in an emulsion made up with simple elixir and acacia in which from 5 to 10 minims are contained in 1 dram.

6. Phenoco is said to be about fifteen times as strong as pure phenol. Hence, if you use phenol in a 5 per cent. solution, a solution of phenoco 1:300 should give an equal effect.

## COMPOSITION AND USE OF GIEMSA STAIN

*To the Editor:*—Please give directions for making up the Giemsa stain, and its use.

E. S. HALL, M.D., McLeansboro, Ill.

ANSWER.—The formula of the Giemsa stain is as follows:

| | |
|---|---|
| *Azur II—eosin* | 3.0 gm. |
| *Azur II* | 0.8 gm. |
| Glycerin (C. P.) | 250.0 c.c. |
| Methyl alcohol (C. P.) | 250.0 c.c. |

Grind up the dyes in the alcohol and then add the glycerin.

Fix the films in methyl alcohol, and stain for five minutes in a mixture of 14 drops of the stain to 10 c.c. of distilled water. If necessary, a trace of sodium carbonate may be added to the water to intensify the basic stains. Wash in water, dry, and mount.

## GREEN PLANTS IN THE SICK-ROOM AT NIGHT

*To the Editor:*—1. Is it advisable to remove living green plants from the sick-room at night?

2. If so, why only at night?

R. M. C.

ANSWER.—1. As a rule, living plants will do no harm in a sick-room even at night. In some cases, however, they give off ethers which may have an unfavorable influence on sensitive persons. It is usually stated that they give off carbon dioxid at night, but the amount of carbon dioxid thus added to the air of a room is not likely to be a serious detriment.

2. No harm can be attributed to the ordinary, or daylight, metabolism of plants, which consists in decomposing carbon dioxid and giving off oxygen.

## TREATMENT FOR URTICARIA AND PRURITUS IN HYPERTHYROIDISM

*To the Editor:*—Please suggest treatment for urticaria and the attendant pruritus in a case of hyperthyroidism.

H. P. ASHE, M.D., Pittsburgh, Pa.

ANSWER.—Attention should be given chiefly to the underlying condition of the thyroid. The digestive organs should be kept in as good order as possible. Rest and quiet should be insisted on. Nervous sedatives might be tried. Calcium chlorid is recommended as a remedy in urticaria and would be worthy of a trial. Local alkaline baths or washes and the various antipruritic agents, such as 1 to 2 per cent. solutions or ointments of phenol (carbolic acid) or menthol, are appropriate.

## DISINFECTION BY FORMALDEHYD AND BY SULPHUR

*To the Editor:*—1. What is the best and most efficient method for disinfecting infected rooms for tuberculosis, typhoid and other contagious diseases?

2. Is burned sulphur a good disinfectant in a closed room?

S. P. HAND, M.D., Demopolis, Ala.

ANSWER.—1. Disinfection with vapors of formaldehyd is regarded as a most efficient method of disinfection at present.

2. Burning sulphur in a closed room in the proportion of 3 pounds of sulphur per thousand cubic feet is a fairly efficient method of disinfection, provided that the surfaces and material to be disinfected are thoroughly wet.

## TRAINING SCHOOL FOR MALE NURSES

*To the Editor:*—Please give the address of a training-school for male nurses. I have been a nurse for a number of years and wish a chance to perfect myself in my chosen work.

ARTHUR WILSON, Redland, Fla.

ANSWER.—So far as we can ascertain there is no school for general nursing in the United States to which men are admitted.

# Medical Education and State Boards of Registration

## COMING EXAMINATIONS

ALABAMA: Montgomery, Jan. 13. Chairman, Dr. W. H. Sanders, Montgomery.

ARIZONA: Phoenix, January 3. Sec., Dr. John Wix Thomas, 200 National Bank of Arizona Bldg., Phoenix.

COLORADO: State Capitol, Denver, January 6. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

ILLINOIS: The Coliseum Annex, Wabash Ave. and 16th St., Chicago, Jan. 14-16. Acting Sec., Amos Sawyer, Springfield.

INDIANA: Room 56 State House, Indianapolis, Jan. 13-15. Sec., Dr. Wm. T. Gott, 56 State House, Indianapolis.

IOWA: The Capitol Bldg., Des Moines, January 6-8. Sec., Dr. Guilford H. Sumner, Capitol Bldg., Des Moines.

MINNESOTA: State University, Minneapolis, January 6-9. Sec., Dr. Thos. S. McDavitt, 814 Lowry Bldg., St. Paul.

NEW HAMPSHIRE: State House, Concord, January 6-7. Regent, Mr. H. C. Morrison, State House, Concord.

NEW MEXICO: Santa Fe, Jan. 12. Sec., Dr. W. E. Kaser, East Las Vegas.

NORTH DAKOTA: Grand Forks, January 6. Sec., Dr. G. M. Williamson, Grand Forks.

OKLAHOMA: Oklahoma City, Jan. 13. Sec., Dr. John W. Duke, Guthrie, Okla.

OREGON: Portland, January 6-8. Sec., Dr. L. H. Hamilton, Medical Bldg., *Portland.*

SOUTH DAKOTA: Capitol Bldg., Pierre, Jan. 13. Sec., Dr. Park B. Jenkins, Waubay.

VERMONT: Montpelier, Jan. 13-15. Sec., Dr. W. Scott Nay, Underhill.

WASHINGTON: Spokane, January 6-12. Sec., Dr. F. P. Witter, Traders' Block, Spokane.

WISCONSIN: Madison, Jan. 13. Sec., Dr. John M. Beffel, 3200 Clybourn St., Milwaukee.

## Illinois September Report

Mr. Amos Sawyer, acting secretary of the Illinois State Board of Health, reports the written examination held at Chicago, September 24-26, 1913. The number of subjects examined in was 16; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 136, of whom 87 passed and 45 failed. Three candidates did not complete the examination and one withdrew. The following colleges were represented:

PASSED

| College | Year Grad. | Total No. Examined |
|---|---|---|
| Georgetown University School of Medicine | (1913) | 1 |
| Bennett Medical College | (1912,3) (1913,8) | 11 |
| Chicago College of Medicine and Surg. | (1911) (1913,25) | 26 |
| Hahnemann Med. Coll. and Hosp., Chic. | (1912) (1913,2) | 3 |
| Hering Medical College | (1913) | 1 |
| Jenner Medical College | (1911) (1913,2) | 3 |
| Northwestern University | (1903) (1910) (1913,3) | 5 |
| Rush Medical College | (1902) (1912) (1913,8) | 10 |
| University of Illinois | (1912,2) (1913,13) | 15 |

## New Jersey October Report

Dr. H. G. Norton, secretary of the New Jersey State Board of Medical Examiners, reports the written examination held at Trenton, Oct. 21-22, 191[illegible] The number of subjects examined in was 9; total number of questions asked, 90; percentage required to pass, 75. The total number of candidates examined was 38, of whom 32 passed and 6 failed. Twenty-six candidates were licensed through reciprocity since July 29, 1913. The following colleges were represented:

PASSED

| College | Year Grad. | Per Cent. |
|---|---|---|
| Georgetown University | (1913) | 77.3 |
| Howard University | (1912) | 81.4 |
| University of Louisville | (1910) | 75.5 |
| University of Maryland | (1910) | 75.5 |
| Harvard Medical School | (1912) | 77.9 |
| Dartmouth Medical School | (1912) | 80.6 |
| Columbia Univ., College of Physicians and Surg. | (1911) | 77.5 |
| Fordham University, College of Medicine | (1911) | 77 |
| Long Island College Hospital | (1911) 83; (1913) 81.2 | 82.5 |

| Medical College of Virginia | (1909) | New York |

The following questions were asked:

ANATOMY

1. Name the valves of the heart; give location, structure and function of each. 2. Trace the superficial lymphatics of the upper extremity to their termination. 3. Internal saphenous vein: Give origin and termination, name its tributaries and veins it communicates with in its course. 4. Describe the knee joint, give blood and nerve supply and actions. 5. Describe the prostate gland and give its anatomical relations. 6. Give source and distribution of the nerves of the palm of the hand. 7. What important parts lie behind the sterno-clavicular joint? 8. Superior mesenteric artery: Give origin, course and parts supplied. Name its branches. 9. In amputation, three inches below the head of the fibula, what arteries are divided? 10. Describe the elbow joint.

PHYSIOLOGY

1. Name the cranial nerves that are exclusively motor. 2. State the functions of the sympathetic nervous system. 3. Name the structures involved in a knee jerk, and state the physiology of such a reflex action. 4. Describe a white blood cell. Where are they formed and what is their function? 5. Name the factors which produce the flow of blood in the veins. 6. Describe briefly the digestion of a meal consisting of bread and butter, beef steak and a cup of sweet chocolate. 7. Give the composition of normal urine. 8. Name the functions of the bile. Give its constituents. 9. What is ciliated epithelium? Where is it found and what is its function? 10. What constitutes the lymphatic system? What forces cause lymph to circulate?

CHEMISTRY

1. What is analytical chemistry, and what is the object of qualitative analysis? 2. Mention the general physical and chemical properties of urine. 3. State the general properties of organic compounds. 4. Describe the processes of fermentation and putrefaction. 5. Explain the terms, reaction and reagent. 6. Explain the process of respiration, from a chemical viewpoint. 7. What is ozone, and how does it differ from common oxygen; under what circumstances is ozone formed? 8. Illustrate by formula the difference between ferrous and ferric salts. 9. Enumerate the metals, salts of which are frequently employed in pharmacy. 10. State the laws of constant and reciprocal proportions.

HISTOLOGY—PATHOLOGY—BACTERIOLOGY

1. Name six fixing fluids. Give formula and uses. 2. Describe the preparation of permanent specimens. 3. Give life history of

blood-cells circulating in the blood-current. 4. Differentiate leukemia and pseudoleukemia. What characterizes a true leukemia? 5. Define edema. Name varieties and causes. 6. Describe abnormal heart sounds. Give causes and varieties. 7. What diseases or conditions cause respiratory disturbances? 8. Describe the colon bacilli group and diseases caused by them. 9. Describe yeast. 10. Name sources, varieties and effects of bacteria in milk.

### MATERIA MEDICA AND THERAPEUTICS

1. Podophyllum. Give official name, active principle, dose, properties and uses. 2. Glyceryl trinitrate. Give official name, dose, properties and uses. 3. Digitalis. Give official name, dose, properties and uses and preparations. Write a prescription containing digitalis for an adult. 4. Give official name, dose, properties and uses of three mercurial preparations. 5. Give official name of calcium chlorid. Dose, properties and uses. 6. Aspirin. Official name, dose, properties and uses. 7. Aconite. Official name, dose, properties and uses. Antidote for overdose. 8. Give etiology and treatment of rachitis. Write a prescription containing phosphorus for a child. 9. Describe the treatment of a case of sunstroke. 10. Ichthyol. Describe. Give dose, properties and uses. In what form would you apply it locally? Write a prescription for same.

### HOMEOPATHIC MATERIA MEDICA AND THERAPEUTICS

1. Differentiate nux moschata and asafetida in hysteria. 2. Differentiate three remedies in follicular tonsillitis. 3. Give treatment for carbuncle. 4. Give treatment for acute uremia. 5. Describe the cough of puls and drosera. 6. Differentiate eupatorium and gelsemium in grip. 7. Name three remedies having aggravation after sleep; after motion; in dampness. 8. Give indications for two remedies in enuresis. 9. Prescribe for: Constipation, with no desire for stool. Rectum seems sluggish; difficult to expel even a soft stool; stools hard, knotty and scanty. 10. Prescribe for: Headache increasing through the day; bursting pain; worse from sneezing or coughing; coated tongue; thirst; gastric derangement.

### PRACTICE (DIAGNOSIS) OF MEDICINE

1. Describe only the prodromal symptoms, giving duration of each, in (a) measles; (b) scarlet fever; (c) chicken-pox, and (d) small-pox. 2. Name five diseases in which the ophthalmoscope is an important aid to diagnosis, giving reasons therefor in each. 3. Define the terms "contagious," "endemical," "epidemical" and "pestilential," and name two diseases in each class. 4. Differentiate sunstroke, cerebral hemorrhage and alcoholic coma. 5. Describe four murmurs of the heart, giving name, cause, and state where each is best heard. 6. Name three causes for specific gravity of the urine (a) under 1010, and (b) over 1030. 7. Differentiate hepatic, intestinal and renal colic. 8. How much, what and how often would you feed a two-months' old bottle-fed infant? 9. Describe a typical case of acute lobar pneumonia in its different stages. 10. Define bronchial breathing. Where is it heard normally? What does it signify when heard elsewhere?

### SURGERY

1. Define hernia. 2. Give symptoms and treatment of ulcer of pylorus? 3. Give indications and technic of operation for ligation of common carotid artery. 4. Differential diagnosis between fracture of upper end of radius and posterior dislocation of ulna. 5. What is varicocele? How would you treat it? 6. Give causes of retention of urine. Give treatment for one cause. 7. Give differential diagnosis between abdominal ascites and a large ovarian cyst. 8. Give technic of paracentesis thoracis. 9. Give diagnosis and treatment of phlebitis. 10. Describe the operation for empyema.

### OBSTETRICS AND GYNECOLOGY

1. Give three causes for post-partum hemorrhage, and describe your procedure for its control in each case. 2. Give symptoms of threatened eclampsia; of actual eclampsia, and of death of the fetus. 3. What is ectopic gestation? Give its symptoms and its course. Differentiate it from ovarian tumor. 4. What is dry labor? How does it differ from normal? What are its dangers? 5. Given a woman in the eighth month of pregnancy, with uterine hemorrhage and increasing exhaustion. Describe your examination of the case; a condition you would find; your diagnosis, and your management of the case. 6. How would you diagnose left-occipito-anterior position; transverse position; breech presentation and face presentation? 7. What is asphyxia livida and asphyxia pallida? Give treatment. 8. Give causes, symptoms, appearance and dangers of cervical tears, and describe briefly the chief steps in an operation for their repair. 9. Describe and give uses or advantages of the following positions: Sims', Walcher's, knee-chest and lithotomy or dorsosacral. 10. Name three conditions which cause a vaginal discharge; give characteristics of each discharge, and give other symptoms which would differentiate the conditions.

### HYGIENE

1. Mention the various methods of house heating, and state which you consider the best for our temperate climate. 2. State a suitable temperature for a sick room. 3. In pneumonia, how would you ventilate the sick room, and at what temperature would you advise it to be kept? 4. Differentiate between a serum and a vaccine; define natural and artificial immunity how may the latter be produced. 5. For what conditions would you examine a child in order to determine the causes of inefficiency in school work? 6. What would be your method of procedure in rendering a malarial district healthful? 7. What prophylactic treatment would be necessary for those who were undertaking this work?

### JURISPRUDENCE

1. Name some of the violent causes of death. 2. How can you differentiate them? 3. What post-mortem findings would lead you to believe death to be due to $\text{H.NO}_3$? $\text{H9.CZ}_2$? [*Sic. Is this a catch question or a misprint? There were at least fifteen other typographic errors in the original copy.—Ed.*] 4. How would you determine whether a woman was pregnant or not? 5. How might such a question affect an individual from a legal standpoint?

# Book Notices

---

**CLINICAL SURGICAL DIAGNOSIS FOR STUDENTS AND PRACTITIONERS.** By F. de Quervain, Professor of Surgery, University of Basle. Translated from the Fourth Edition by J. Snowman, M.D. Cloth. Price, $7 net. Pp. 779, with 514 illustrations. New York: William Wood & Co., 1913.

If this work were to be described by a single word, that word would be "practical," as the effort of the author throughout has been to present the subject of diagnosis in the most practical manner, eliminating much that perhaps is of scientific interest but as yet of little clinical value. One is constantly reminded that it is a living patient with whom the surgeon has to deal and that the chief aim of diagnosis is proper treatment. This is well illustrated by the following sentences from the discussion of intestinal obstruction: "There is no object in being able to proclaim at the autopsy that we had correctly diagnosed the situation and nature of the obstruction. Our main object must be to diagnose when surgical relief should be offered, although we may not always know the precise position and character of the obstruction."

After presenting the subject in detail the author has the happy faculty of epitomizing or drawing a short conclusion containing the pith of the matter which is easy to remember. For instance, with reference to injuries of the brain we find this: "The following conclusion may be drawn for the diagnosis of contusion of the brain. A patient who, immediately after an injury to the skull, manifests brain symptoms which persist for a whole day and which do not fit in with the signs of a gradually increasing cerebral pressure, has sustained a contusion of the brain in the widest sense of the term. This view is supported by the presence of irritative or localizing symptoms arising from cortical areas of ascertained function. It is definitely confirmed by a persistent rise of temperature which cannot be explained by infection from without."

The method pursued by the author in arriving at a diagnosis is to reason from the symptoms to a conclusion either on positive evidence or by exclusion, rather than to assume a definite condition and arrange the symptoms to fit the condition. While technical methods are not omitted, the author has "employed those methods of investigation which are available for the general practitioner, or at any rate, which can easily be carried out for him." The illustrations, which are numerous, are quite good and almost all of them are taken from the author's own cases.

**PROTEIN SPLIT PRODUCTS IN RELATION TO IMMUNITY AND DISEASE.** By Victor C. Vaughan, M.D., LL.D., Dean of the Department of Medicine and Surgery of the University of Michigan, Victor C. Vaughan, Jr., M.D., A.B., Junior Attending Physician to Harper Hospital, Detroit, and J. Walter Vaughan, M.D., A.B., Junior Attending Surgeon to Harper Hospital, Detroit. Cloth. $3 net. Pp. 476, with illustrations. Philadelphia: Lea & Febiger, 1913.

This is a compilation and summation of the work which has been carried on for many years in Vaughan's laboratory at the University of Michigan. As is well known by those in touch with the progress in infection and immunity, this work began with a study of the composition and disintegration products of bacterial cells, which led to the finding of certain toxic and non-toxic products that were afterward learned to be obtainable also from proteins of all sorts. Out of this work, which incidentally yielded many items of value concerning bacterial chemistry, came also knowledge of changes which take place in foreign proteins within the animal body, whether these foreign proteins are bacterial cells, injected serums or food proteins. The ideas and results thus obtained preceded much of the modern investigation of protein sensitization and intoxication —that is, anaphylaxis or allergy. Vaughan is recognized as one of the pioneers in this most important line of progress, his work having been of particular value because it approached the subject from the chemical side at a time when practically all the investigation was solely by animal experiment. The conception of anaphylaxis as an intoxication with the products of protein disintegration, formed through the action of specific ferments developed as a biologic reaction to the foreign proteins and an integral part of the scheme of immunity to infection, was original with Vaughan, and has since been corroborated and developed at length by many other investigators, so that it is now the current theory of anaphylaxis. These American studies foreshadowed the work on "anaphylatoxins" and "protective ferments" in association with which the names of Friedberger and Abderhalden are especially conspicuous at present.

In addition to the work which has been done under the inspiration of the senior author, the book reviews much of the work of other investigators which bears on the subjects under discussion. There is also a presentation of the underlying principles and the conclusions which have been reached. While the authors are concerned primarily with presenting certain original work for consideration, the general air of fairness to other workers, and of seeking for the truth rather than insistence on unqualified acceptance of their own hypotheses, is noticeable and commendable. The collection and discussion of this large amount of material, which has heretofore been widely scattered in the literature, will be of great assistance to other investigators and to students of immunity in general. In the history of the early steps of our study of the important field of allergy this contribution will hold a prominent place. We would criticize but one thing—the title. "Protein Split Products" is an awkward but common translation of the German *Spaltungsprodukte*. It is not the split products of protein, nor yet protein split products—it is the products of protein-splitting, or better, cleavage, that we have under consideration.

Innere Sekretion. Ihre Physiologischen Grundlagen und ihre Bedeutung für die Pathologie. Von Prof. Dr. Artur Biedl. Second Edition, Part II. Paper. Price, 28 marks. Pp. 692, with 75 illustrations. Berlin: Urban and Schwarzenberg, 1913.

This completes the second volume of the new and greatly enlarged second edition of this, the most exhaustive and authoritative of all the treatises of the glands of internal secretion. The general characteristics of the book have been sufficiently discussed in our reviews of the first edition and of the first volume of this edition. In the second volume are found the completion of the discussion of the adrenal, and the sections on the carotid and coccygeal glands, the hypophysis, the pineal gland and the internal secretions of the sexual glands, pancreas, alimentary canal and kidneys. As bearing eloquent testimony to the use the German readers expect to make of their books is the publication of a bibliography of 260 pages. It is scarcely necessary to say that even this imposing array of titles entirely fails to comprehend all the really valuable contributions that have been made to the subject of internal secretions, but it is by far the best compilation yet made, just as the book represents the best available source of information in this field. Because of the author's critical consideration of so much of the enormous literature, and especially because he speaks with the insight obtainable only by one who has himself made investigations of importance to the subject. this work is to be unqualifiedly recommended as the most reliable and useful work on the ductless glands and internal secretions that has yet been produced.

Mendel's Principles of Heredity. By W. Bateson, M.A., F.R.S., V.M.H., Director of the John Innes Horticultural Institution. Cloth. Price, $3.50 net. Pp. 413, with illustrations. New York: G. P. Putnam's Sons, 1913.

The author states that in writing this book it was his object to give a succinct account of discoveries in regard to heredity made by the application of Mendel's method of research. Among the biologic sciences, of which medicine is one, the study of heredity occupies a central position, and there can be no doubt that a perception of the truth in regard to the function of transmission will greatly contribute to the progress of medicine as well as to sociology and the industrial arts of the breeders of plants and animals. Bateson describes the original experiments of Mendel, defines "dominant," "segregation" and "allelomorphism," considers the consequences of segregation and the meaning of purity of type, and gives a list of sixty-one structural characters already proved to follow the rules of mendelian inheritance. To the complicated question of the heredity of color about a third of the book is devoted. The investigations on the more important problems of heredity and sex are sketched, and the scanty evidence as to mendelian inheritance in man considered. Of normal characteristics the dominance of eye pigment is about all that is certainly established. The complexity of the transmission of color characteristics is great. More is known of the transmission of disease and malformations which are in general dominant. A synopsis of the studies of Farabee, Drinkwater and Walker of brachydactyly is given in some detail. Color-blindness is considered among the sex-limited affections. In the discussion of human heredity it is stated that nothing in our present knowledge can be taken as a reason for regarding consanguineous marriages as improper or especially dangerous. Rules are given for the collection of evidence as to human descent. Intermediates between varieties and miscellaneous exceptions and uncomparable phenomena are considered in detail, and here as in other parts of the book the author criticizes "the law of ancestral heredity" of Galton, and the method of investigation pursued by Pearson and the English biometric school. The bearing of the mendelian discoveries on biologic science is sketched, and the nature of the unit characteristics, nature and moment of segregation, the relation of the chromosome to the unit factors, as asymmetry and variations and reversal of varations are discussed, as well as the bearing of the theory on evolution. The appendix contains a short biography of Gregor Mendel, with translations of his papers on hybridization and *Hieracium*.

Eye-Strain in Every-Day Practice. By Sydney Stephenson, M.B., C.M., D.O., Ophthalmic Surgeon to the Queen's Hospital for Children, London. Cloth. Price, $1.50 net. Pp. 139. New York: Paul B. Hoeber, 1913.

This is a collection of articles on eye-strain published by the author during the past ten years, the last one being the Middlemore postgraduate lecture delivered in Birmingham in December, 1910. Mr. Stephenson well represents the newer ophthalmology. He is one of those who study the patient as well as the eye, and whose interest is not entirely absorbed by pathology and surgery. With reference to eye-strain as the cause of all our ills, he takes a wise middle ground, criticizing both the extreme enthusiasts and the unbelievers. He quotes many cases from his large experience which aptly illustrate the common and the uncommon effects on comfort and health of uncorrected and imperfectly corrected errors of refraction. He emphasizes repeatedly the importance of complete cycloplegia in the study of these cases, and puts no age limit on the use of cycloplegics. He calls attention again and again to the often overlooked fact that perfect vision is not at all inconsistent with eye-strain, and that it is the small and easily concealed error that often causes the most persistent and annoying headache, nausea, vertigo or other symptom. It would be well if every practitioner, and especially every neurologist, would read and ponder these essays. The references to the literature on the subject are worth the price of the book to any one interested. The references to the work done in America, beginning with the classical papers of Dr. Weir Mitchell, are especially gratifying.

Gout. Its Etiology, Pathology and Treatment. By James Lindsay, M.D., M.R.C.P. Cloth. Price, $1.50. Pp. 212. New York: Oxford University Press, 1913.

This is a well-written, concise statement of facts and theories pertaining to gout. The author has analyzed statistics in an interesting way. The chemistry of gout is discussed, but nothing is contributed to our knowledge of the subject. The brief chapter on the bacteriology of gout is interesting, as it briefly outlines the various theories which have been published assigning to bacteria a causal relationship to the disease. These theories, however, are not sufficiently substantiated by facts. The clinical description of typical gout is excellent and is accompanied by pictures of joints, ears, eyelids and finger-nails which are extremely good. Roentgenograms are also reproduced and help the reader to understand the pathology of the disease; but this part of the book is open to criticism because atypical gout is too briefly and imperfectly described. There is nothing new in the treatment outlined by the author. What he advises is conservative and praiseworthy.

# Miscellany

## The Diary of a Dublin Medical Student (1831-1837)

In the *Dublin Journal of Medical Science* for November, 1913, p. 360, Dr. T. Percy C. Kirkpatrick, registrar of the Royal College of Physicians of Ireland, prints the diary of Robert Thompson, M.D. (Glasgow, 1838), during his student period at Steevens' Hospital and the School of the Royal College of Surgeons in Dublin (1831-1837). Thompson, after graduation, commenced practice in Johnstown County, Kilkenny, where he worked with conspicuous success as surgeon and obstetrician until his death, April 8, 1875. Having been apprenticed to Abraham Colles in October, 1831, with what he calls "a pretty fair, though not well-grounded, education," he began to attend lectures while in residence at Steevens' Hospital, "where a number of wild fellows messed in our room, generally spent our evenings sparring and drinking punch and going to the upper gallery at the theater." Cholera appearing in Dublin in April, 1832, he was attacked with "nostalgia and other nervous symptoms, which disappeared immediately upon my reaching home on Easter Sunday, 1832." Returning to Steevens in October, he began to work hard at dissecting but was soon laid up with small-pox caught from a subject. In 1833-1834 his chum was William Colles, son of the famous surgeon, with whom he "spent a jolly winter, drank a deal of punch, went to the theater at least twice a week, passed the second examination May, '34." Most of his time through his whole student's career was taken up with a pleasant combination of conviviality, outdoor life and hospital work, diversified by other Irish experiences, of which we may give a few citations:

Nov. 15, '33: I am on duty to-day, and had a good deal to do in the way of dressing fractures; took in an old man with a broken humerus. At present there are only six resident pupils in the house besides Tuthill.

July, 1834: Read some Béclard's "General Anatomy." . . . Have paid nurse in advance until Dec. 9, 1834. [The nurse in those days usually looked after the resident students' rooms and laundering for a consideration.] Read very hard for two months for the third class examination, which I passed on November 15.

May 22, 1835: I have been examined to-day by Hart on the physiology of the nerves, next on the anatomy of the prostate and prostate glands, of which I missed not a word; then on the blood tumour of the scalp. Adams on Medical Jurisprudence.

March 1, 1835: Got a green frock coat from Walker.

May 24, '35: Have been made an Orangeman to-day; fee 7s. 6d.; paid Bryan 1s. 6d. for washing; sundries 3s. 6d.

June 2, '35: Paid Benson £2 2s. for dissection; dined at Finish, 2s. 2d.

June 11, Monday: I am completely stuck for money; have not written home.

June 26: Slept badly; bought 5 pounds of tea; Mun and I dined at the Northern; borrowed £1 from John Hely.

July 3: Went with crew of six to sea; the swell was too heavy at the lighthouse; did not go past it; had a great lunch and heavy drink on the wall.

Tuesday, July 30: John Hely called here to-day; dined with him at the hospital; saw a contused and lacerated wound of the ankle from the ball of the great toe to the inner side of the os calcis, which was rough, and the tendon almost divided, the posttibeal nerve quite bare, and the artery could be seen pulsating; the posttibeal tendon was bared. Mr. Harrison put in three points of suture, one anterior, one under the malleolus and another posterior to it; the wound dressed with lint dipped in blood; there were globules of synovia in the blood.

August 2: Went with Mun to Marradyke after plover.

Sunday, 10: Walked to Templetuohy Church; beat the car there and back; while coming home fell into a ditch.

Wednesday, 13: Commenced to write a translation of Lucian. . . . Went to Ballyknockan in the evening; fell off the mare.

Saturday, 16: Went in the car to church; poulticed my leg; continued poultice; reading Lucian.

October 29, '35: Tom Neville is dead; got a pair of Trews; Henry is gone to Kilkenny; my hand very sore where the cow bit me in endeavoring to extract a potato from her throat.

Dec. 5, '35: Bought a hat, £1 3s.; paid Evans 2s.; paid O'Keife for putting down my name for lectures £4 4s.; received from Henry to pay gun 15s.; ordered a coat from Gately, £3 10 s.; paid Maunsell 5; boots vamped, 12s. 6d.; attended my first midwifery case.

Monday, Dec. 14, '35: Visited the Meath Hospital; went round with Graves; will attend there; was called up four times last night.

December 22: The weather is very cold; thermometer in my room 8 below zero; had a case in Trinity place; retained placenta; got Maunsell to extract it.

Dec. 25, X Mass: The woman in Trinity Place is very well, but the pulse is 130; no pain in the hypogastrium, but a very slight tenderness; no fever.

Jan. 12, '36: We have established a mess; got a receipt from the butcher for £3 11s. 6d.

February 10: Received a cheque for £5 to pay for tea.

February 15: Had a breech presentation in Mary Street.

March 22: Saw Cusack tie the carotid for aneurism.

April 8: The statue of King William blown up.

April 25: Painting the boat.

April 26: Saw a flap operation of forearm.

April 27: Got my certificate, M. Medica, M. Jurisprudence, Surgery.

May 8: Moore and Hunter (who are both dead since, one in Limerick and the other at Madras) returned from Glasgow; we all, with Gelstone, supped at O'Hara's, on leaving which place we got up a row with two watchmen, who were well beat; they got away, however, and brought back twelve others, who soon turned the tables; Somerville was knocked down and eight of us arrested and fined 30s. each. Lent J. Hely £1; he and Chas. came here to-day.

May 19: Returned Gerald Osbrey's pistoll and thermometer.

May 24: Had a breach case to-day.

June 4: Reading Cooper on the testicle; wrote home.

June 17. Grind on exostoses, a desease [*sic*] of which I know very little.

June 26: Dined in a cabin, consumed a deal of mountain dew.

June 28: Dissecting.

June 29: Dissecting.

July 26: Dined at Steevens' with W. Colles.

August 8: At a case of twins with Maunsell for nineteen hours.

October 12: I am 20 to-day; dined at O'Hara's in the evening; at Bull's got into a fight; Brown and I well beat by six or seven fellows; J. Hely lodged a pound for him and me; in the morning went to College Street; no prosecution.

Jan. 17, '37: Have put in my first day's examination taken by Palmer on the testicle hernia, by Hart on General anatomy of, by Harrison on fauces, Tongue.

January 23: Passed the College; examined by Rumly on fever, by Mr. Colles on inflammation of bladder, naevi; answered well.

January 24: Hair cut; went to the Protestant meeting.

January 27: Received from my father £10.

January 31: Became very ill this morning with sore throat and fever.

February 1: Sent for Colles; confined to bed for a week with influenza.

January 13: Had my certificate of residence signed by Cusack, Wilmot.

June 22: I must go to Dublin for my diploma.

Although he became a licentiate of the Royal College of Ireland, in 1837, Thompson did not graduate at Dublin, but took his degree at Glasgow a year later. In spite of his fondness for skylarking and conviviality, he seems to have been a good student and a successful practitioner. On the whole a graphic, if sketchy, presentation of a medical student's life in the late thirties, the palmy days of Colles, Stokes, Adams and the other leading lights of the Dublin school.

**Defective Schoolchildren.**—The medical examination of schoolchildren in New York, which became compulsory under the law in 1913, was begun in 1907 as volunteer work by the State Department of Health. During the first years of this work the statistics were not considered reliable, but during the past year the work has been so extended and systematized that the results, while lacking in some details, are still worthy of consideration. The total registration in the public schools of the state last year, exclusive of the cities, was 415,930. Of this number 30 per cent. were examined for physical defects by the teacher. The exact number reported as having some defect of sight, hearing, nasal respiration or the teeth has not been carefully determined, but will be about 30 per cent. The total number of defective children found in the 124,526 examined was 81,867, being 65.6 per cent. The highest percentage of defects was shown in the teeth, 29.7 per cent. having defective teeth. This percentage is thought to be much too low, as Buffalo schools showed a percentage of 46.7 per cent., and in the New York City schools an examination of the reports of 23,000 children in fifteen schools shows a percentage of about 50 having defective teeth. Next to teeth the largest number of defects was found in distant vision, 25.8 per cent. The percentage of defects, except those of the eyes, decreased with advancing age. In the departmental reports there was no decrease in those having colds or suffering from catarrh, 14.6 per cent. being subject to frequent colds. There were 13,195 reported as being mouth-breathers, and 34,020, or 27.9 per cent., as having defective teeth, and 2.5 per cent. as not being up to the standard of health of the other children or as being truants. In New York City about 14 per cent. were found to be mouth-breathers. This tabulation shows that distant vision decreases about 9 per cent. between 7 and 16 years of age; discharging ears 29 per cent. There was also a decrease of 28 per cent. in frequent earaches between the ages of 13 and 16, and 32 per cent. in deafness between the same ages. There was an increase between the ages of 7 and 16 of 13 per cent. having inflamed eyes or squinting; of 41 per cent. in headaches; 35 per cent. in those having frequent colds, and 92 per cent. in those wearing glasses. There was an increase of 25 per cent. between 13 and 16 years of age in the focusing power; 24 per cent. in the mouth-breathers, and 32 per cent. of those having defective teeth. Backward children increased 62 per cent. between 7 and 13 years of age, and those having defective hearing 16 per cent. The defects noted in the New York reports are about the same as those of Massachusetts.

**Advent of the Socialized Man of Service.**—The commercialized man only is passing; the socialized man of service is arriving. The eyes of the world have been focused on commercial conquest without considering the man-portion of the problem. We are entering on a forward movement of humanity when man will count for more than dollars; the age of the child, home and sanitation; an age when a captain of preventive disease and crime will be hailed with equal acclaim as a captain of industry. . . . The Chicago Woman's Club, parental schools, home and truancy movements, boy scout movement, juvenile courts are skirmish lines behind which the social forces of the nation are aligning. Prevention of disease and crime is the shibboleth of the race-betterment workers. The workers in this field are determined that the needs of the home, school and sanitation shall be brought up abreast with commercial and industrial activities; that America shall no longer be the home of preventable diseases and preventable crime; that this republic, as originally designed, shall be the home of the child, the mother, the toiler in every productive and constructive field of labor.—D. E. McClure, *Bull. Mich. State Board Health.*

**Infusion Method of Treating Varicose Veins.**—B. Schiassi of Bologna, Italy, has recently issued a pamphlet, profusely illustrated, showing the details of his method of flushing the vein with an aqueous solution of iodin. The principle is not new, but the substances used for the purpose hitherto have had more or less of a caustic action, and this, he declares, is wrong. The fluid he uses merely stimulates the inner lining of the vein to proliferate; this obstructs the lumen, and the tendency to varicose enlargement is thus arrested. He severs the vein through an incision about 6 cm. long, below the knee and again in the upper third of the thigh, or else at the ankle, according to the location of the principal trouble. He then injects the fluid into the vein from the upper stump in the lower incision, and the fluid pours out of the distal stump in the upper incision. He makes the infusion through a glass tube 2 or 3 mm. in diameter, with an olive tip with a single large window; this end is worked into the vein; the other end is connected with the syringe by a rubber tube. The fluid is a mixture of 1 gm. metallic iodin, 1.1 gm. potassium iodid and 100 gm. distilled water. The method has been applied in hundreds of cases with invariably satisfactory results, he states, and adds that embolism is impossible with this technic. The solution prevents instead of favoring coagulation, and the stumps not utilized are ligated. We will loan the pamphlet on request accompanied by three 2-cent stamps.

### Liability of Company Contracting to Furnish Employees with Physician

*(Neil vs. Flynn Lumber Co. (W. Va.), 77 S. E. R. 324)*

The Supreme Court of Appeals of West Virginia holds that when an incorporated lumber company agrees with an employee, in consideration of monthly deductions therefor from his wages, to furnish a competent and skilled physician to attend and treat him for any sickness or accident occurring while in its service, it is bound thereby to select and retain for that purpose a physician having the knowledge and skill ordinarily possessed by other members of his profession in the same community.

Should the company fail to perform the duty so imposed, and by reason thereof the employee be injured, it will be liable in damages to him, to the same extent as the physician himself would be were he sued for the injury. In such a case, the injured employee may maintain against his employer either what is termed an action in assumpsit on the contract, or trespass on the case for the tort.

The contract stated is not ultra vires, or beyond the corporate powers of the company to make.

It is true that the relation of master and servant, principal and agent, has no application as between a corporation and a surgeon employed by it to render professional services to its sick or injured employees, and that the doctrine of respondeat superior, or let the superior answer, has no application. But this rule is subject to the important proviso that there is a liability on the employer to the servant unless in pursuance of its undertaking it exercises reasonable care in selecting one having the knowledge and skill ordinarily possessed by other members of his profession in the same community.

### Damages for Alleged Malpractice in Treatment of Shoulder

*(Stanford vs. Hyde (Conn.), 87 Atl. R. 738)*

The Supreme Court of Errors of Connecticut, in affirming a judgment in the plaintiff's favor for $2,000 damages for alleged malpractice, says that in the conflict of the testimony the jury might reasonably have found that a fall from the ladder was the cause of some injury to the plaintiff, and that if the shoulder was thereby dislocated the defendant ought in the exercise of reasonable care to have discovered it. The most serious issue of fact in the case was whether or not one of the injuries suffered by the fall was a dislocation of the shoulder. There was evidence before the jury from which the existence or non-existence of this fact might have been found. The court cannot hold that the jury in finding its existence acted so unreasonably as to warrant the setting aside of the verdict. Nor can the court hold that the damages assessed by the jury were so excessive that the verdict ought for that reason to be set aside, when the special damages might have been found to be $478 and the injury to have resulted in an appreciably permanent impairment of the shoulder affecting the plaintiff's pursuit of his trade.

### Must Have and Exercise Skill

*(Hinkle vs. Smith (Ga.), 77 S. E. R. 650)*

The Court of Appeals of Georgia, in affirming a judgment for the plaintiff, says that the evidence was conflicting, but the evidence for the plaintiff supported her contention that she sustained damage by reason of the unskilful manner in which her dislocated shoulder was reset by the defendant, although a finding would have been authorized that the shoulder was properly set, and the plaintiff's injury was the result of a redislocation, brought about from causes over which the defendant had no control. The evidence authorized a finding that the plaintiff had been damaged by reason of unskilful surgical treatment by the defendant.

Even if the instructions of the court to the jury which were complained of could be construed as submitting to the jury the issue as to whether the defendant possessed reasonble surgical skill, they were not erroneous. The jury being authorized to find that the defendant failed to exercise a reasonable degree of care and skill, it was wholly immaterial whether the injury to the plaintiff resulted because the defendant did not possess reasonable skill as a surgeon, or whether, having such skill, he failed to exercise reasonable care in the treatment of the plaintiff.

One undertaking to practice medicine or surgery must bring to the exercise of his profession a reasonable degree of care and skill. If, in performing an operation, a surgeon fails to exercise such a degree of care or skill, he will be liable for any damage which may ensue, without reference to whether he did not possess the requisite amount of skill or whether he negligently failed to exercise skill which he did possess.

### Medical Services Not a Consideration for a Release

*(Kennedy vs. Spokane, Portland & Seattle Railway Co. (Wash.), 132 Pac. R. 50)*

The Supreme Court of Washington says that the plaintiff was injured while in the employ of the defendant. Subsequently he went to the company's offices and there saw the claim agent, also the company's head physician, and was presented by the claim agent with a written release of damages with the request that he sign the release, which he did. This release recited that, in consideration of medical and surgical attention furnished to him by the company, he released it from all liability, etc. The first question to be determined was: Did the medical services furnished by the company's physician to the plaintiff constitute a consideration for the release? If the rendition of these services by the physician and the acceptance of them by the plaintiff did not create the relation of debtor and creditor between them, then the services would not be a consideration for the release. In other words, if they were rendered under such circumstances that a recovery could not have been had for them in an action against the plaintiff, then they would be insufficient as a consideration. It was not contended that the evidence failed to make out a prima facie case of negligence on the part of the company which caused the original injury. When negligence is once established, the person or corporation being guilty thereof becomes liable for the expenses incurred for medical attention and physician's services. And, on the hypothesis that there was negligence which produced the original injury, the services of a physician, being an element of legal liability, would not be a consideration for the release of damages.

### Testimony as to Roentgen-Ray Pictures Without Their Production—Not Best Evidence

*(Marion vs. B. G. Coon Construction Co. (N. Y.), 141 N. Y. Supp. 647)*

The Supreme Court of New York, Appellate Division, Third Department, says that in this personal injury case one of the plaintiff's witnesses, a physician, after testifying that he was present when certain Roentgen-ray pictures were taken, saw them taken, saw them developed, and looked at the plates immediately after they were developed, proceeded to tell what the pictures showed. Another physician also told what he thought the plates showed. There was no demand made by the defendant for the production of the plates; no hint or suggestion that they were desired. They were in fact in court, so the plaintiff stated in his brief. The court can see no error at all in this Roentgen-ray incident. The evidence showed that nobody but a Roentgen-ray expert could tell anything from the plates, and that if they had been produced they would have done the court, jury, or the defendant's ordinary physicians no good.

The court does not think that the doctrine that an ordinary photograph is the best evidence of what it contains should be applied to Roentgen-ray pictures. They constitute an exception to the rule concerning ordinary documents and photographs, for the Roentgen-ray pictures are not, in fact, the best evidence to laymen of what they contain. Generally they are no evidence at all, signifying nothing whatever, except to the expert. The opinion of the expert is the best evidence of what they contain—the only evidence.

If there had been a demand for these pictures in court, or a request that they be submitted to the inspection of the opposing experts, and these rights had been denied the defendant, such an error would be serious. But whatever harm befell the defendant, if there was any harm at all, came to it by reason of its own failure to demand what it was entitled to, and what it would unquestionably have received by the mere asking. To sustain this contention of the defendant would be to tolerate worse than a technicality—a trick.

### Sufficiency of Complaint in Action for Malpractice—When Barred

*(Finch vs. Bursheim (Minn.), 142 N. W. R. 143)*

The Supreme Court of Minnesota affirms an order overruling a demurrer to the complaint in this action for alleged malpractice in the treatment of a dislocated hip joint. The court holds that the allegation that the defendant "negligently and unskilfully" treated the injury after undertaking the case was clearly sufficient as against a demurrer. Perhaps a motion to make the complaint more definite and certain might have been sustained, but it was not open to serious question that the complaint stated a cause of action.

The court also holds that an action against a physician and surgeon to recover damages due to negligent and unskilful treatment of the plaintiff is based on a breach of his contract to treat the plaintiff with ordinary professional skill and care, and is an action on contract. It is therefore not barred by the provision of the Minnesota statute of limitations which provides that actions for libel, slander, assault, battery, false imprisonment, or other tort resulting in personal injury shall be commenced within two years. The six-year limitation applicable to actions on contracts applies.

### Proof in Action for Services in Another State

*(Corcia vs. Giuliano et al. (N. J.), 87 Atl. R., 94)*

The Court of Errors and Appeals of New Jersey affirms a judgment of the Supreme Court affirming a judgment for the plaintiff, a physician, obtained in the district court of East Orange, N. J., against the defendants, who were husband and wife, for medical services rendered their daughter in the city of New York. The court holds that a motion for a nonsuit was properly denied, which asked for the nonsuit on the grounds: (1) that the plaintiff had not introduced in evidence his license as a physician and surgeon in the city of New York; (2) that the plaintiff had not deposited with the clerk of Essex County a copy of any diploma of a legally chartered medical college or university in good standing, or some medical society having power by law to grant diplomas.

### Power of Boards of Health to Regulate Removal of Dead Animals

*(Schwarz Bros. Co. vs. Board of Health of Jersey City (N. J.), 87 Atl. R. 463)*

The Court of Errors and Appeals of New Jersey holds that a municipality may lawfully make reasonable regulations prescribing the time within which the dead animals may be removed or disposed of and the manner of such disposition. The sole justification for the exercise of this power is the conservation of the public health. An ordinance passed by the board of health prescribing such regulations is valid so far as it relates to dead animals which are a nuisance or offensive or likely to be dangerous to the public health; but there does not seem to be any sound or valid basis for a provision in the ordinance which requires the owner to obtain a special permit before the removal of the carcass, where the dead animal is not a nuisance and not offensive or dangerous to the public health by reason of the disease or diseases of which it died or for any other reason, and therefore in that respect and to that extent the ordinance is unreasonable. Moreover, the court deems beyond the powers of the board a provision in such an ordinance which delegates to the health officer the power to determine when and under what conditions a permit shall be granted to the owner of a dead animal for its removal. That is a delegation of power which should be exercised by the board of health itself.

## SOUTHERN MEDICAL ASSOCIATION

*Seventh Annual Meeting held at Lexington, Nov. 17-19, 1913*

The President, Dr. Frank A, Jones, Memphis, Tenn., in the Chair

### Cerebrospinal Meningitis with Special Reference to Certain Signs or Measures

Dr. Randolph Lyons, New Orleans: The relative importance of Brudzinski's signs in adults has not been determined carefully. From the point of view of early diagnosis the eight measures fall into the following order of importance: Lumbar puncture established the diagnosis in 95 per cent. of the twenty-one cases which I analyzed. Rigidity of the neck could be demonstrated in twenty cases on first examination, or 95 per cent. Kernig's sign was present on first examination in 90 per cent. of the cases and at some time during the disease in 100 per cent. The "neck sign" falls into fourth place. Brudzinski's statement with regard to the relatively greater value of his "neck sign" over Kernig's sign in children does not hold good for adults. It was found positive on first examination in 76 per cent. of the cases and could be elicited at some time during the course of the affection in 90.4 per cent. Brudzinski's contralateral (identical) reflex was present on first examination in only 33.3 per cent. of the cases. It was positive at some time during the disease in 50 per cent. of the cases. Babinski's sign occurred in but three cases, or 11.6 per cent., at some time during the disease. In two of the cases it was positive on admission. Macewen's sign was found to be of practically no value in this series. It could be demonstrated in but one instance. This patient was the only child (5 years) in the group. The presence or absence of the patellar reflex was found to be of no apparent diagnostic importance.

### Meningococcus Carriers

Dr. William Litterer, Nashville, Tenn.: The viability of the meningococcus isolated from carriers varies greatly in different epidemics. The variability in the resistance is not a reliable index as to the degree of toxicity of the microorganism. The meningococcus appears to be of so short vitality and so fragile an organism outside of its natural habitat (the human body) as to lead to the inference that direct transmission is probably the only means of conveying the disease. The great majority of healthy persons who harbor the organism can resist the infection. Only 2 per cent. of the carriers in our series developed the disease. The spray cannot reach all the deep recesses of the upper air-passages; nevertheless it is indicated in all carriers, for the reason that it either destroys or mechanically cleanses out all cocci with which it comes in direct contact, thereby lessening reinfection, and at the same time reducing droplet infection to the minimum. There is apparently no means at our command in which the "persistent carrier" can with any degree of regularity be rendered free from the carrier state. In institutional epidemics the wisest procedure is a prompt isolation of all patients, the search for carriers and their detention, together with the general use of the spray.

### The Intrameningeal Treatment of Tabes Dorsalis and Cerebrospinal Syphilis

Dr. Thomas R. Boggs and Dr. R. R. Snowden, Baltimore: We treated by the intraspinal injection of serum removed one hour after the intravenous injection of salvarsan or neosalvarsan. The Swift and Ellis technic was followed, except that we injected larger doses of the undiluted serum. Blood was withdrawn one hour after the intravenous administration of salvarsan and allowed to clot. The next day the serum was removed, centrifugalized and heated at 56 C. (132.8 F.) for half an hour. Lumbar puncture was then done, cerebrospinal fluid withdrawn and exactly enough serum injected to replace the fluid. The amounts varied between 20 and 35 c.c., and the treatment was repeated from every ten to twenty days until the spinal fluid was normal in respect to the cell-count and Wassermann. In every case there was marked improvement, the cell-count dropping to normal and the Wassermann becoming less marked and in most of the cases entirely negative. The most constant result was the disappearance of the lightning pains and other sensory disturbances, and this resulted in a more cheerful mental attitude and a corresponding improvement in the appetite and nutrition. The effect on locomotion was slower in development and less marked, but definite, and in some cases great improvement was achieved, rather more pronounced, apparently, than in patients treated by smaller doses of diluted serum.

#### DISCUSSION

Dr. R. H. von Esdorf, Mobile, Ala.: The best thing to do is to isolate the patients as early as possible and surround them with the best conditions that can be had, which in many cases is not feasible at the homes of the patients. If a small hospital could be established and the patients isolated, it would lower the mortality from this disease materially.

Dr. Lillian H. South, Bowling Green, Ky.: For one case in which a diagnosis of meningitis was made from a swab of cotton sent in a sterilized container to the laboratory there developed one hundred cases in one town, with thirty-five deaths. Three counties were infected. The child from whom the swab was taken died before it could receive the serum. Another child in the same family was seriously ill from meningitis.

Dr. C. C. Bass, New Orleans: Rigidity of the neck is an important sign in connection with the diagnosis of meningitis. Meningitis is accompanied constantly by fever. These two signs are sufficient to justify a suspicion of the presence of meningitis. Lumbar puncture is indicated, with examination of the cerebrospinal fluid.

Dr. L. E. La Fetra, New York: Pneumonia may simulate meningitis, and if there is suspicion of meningitis. lumbar puncture should be made. In certain cases of poliomyelitis there will be fever and, at times, leukocytosis and stiffness of the neck. These are the cases which have marked sensory symptoms and hypersusceptibility of the nervous system generally.

Dr. L. W. Elias, Asheville, N. C.: The directions are to give one dose of serum every day for four days, and if the patient improves, to wait and watch. Other directions which seem to be more accurate are to give the serum until the fluid is germ-free.

Dr. C. C. McLean, Birmingham, Ala.: I have seen two cases of sudden death following injection of the serum. The blood-pressure should be taken along with the injection, and as soon as the blood-pressure begins to rise, the injections should be stopped.

Dr. Henry Hanson, Jacksonville, Fla.: The use of autogenous vaccines is not of much benefit in carrier cases. A great many of these are simply mechanical carriers, and the organisms are not very closely associated with the circulation of the individual; hence it would be unusual to expect a vaccine to be very efficacious. Another point to consider is the virulence of the organism in carrier cases.

### Milk in Its Relation to Infant Mortality

Dr. Henry Enos Tuley, Louisville, Ky.: The formation of infant-welfare associations is one of the ways to reduce infant mortality. The medical profession is remiss in not taking a more active part in all social service movements and should help to organize an association for the distribution of clean milk. The work of the nurse in the homes is also a great help. Under no circumstances should swill be fed to dairy cattle, even if legislative enactment is necessary before the practice is stopped. Recent investigations have pointed out a new menace, namely, the infection of cow's milk with the *Bacillus abortus*, and it has been advocated that certified milk as well as market-milk should be pasteurized, or preferably boiled under official supervision. Milk is a carrier of contagion, and it can be rendered safe possibly for the market-supply by pasteurization or sterilization. These procedures should be under the supervision of municipal control, and the consumer educated in the care of the milk in the home.

### Treatment and Cure of Malaria

Dr. C. C. Bass, New Orleans: Perhaps the most perfect specific in medicine is quinin for malaria, but it is a specific only when administered properly. The asexual cycle of malarial plasmodia which causes the common symptoms of malaria in man takes place partly in the blood-stream and partly in the capillaries. The plasmodia lodge in the capillaries and remain until they segment. The time spent lodged in the capillaries varies with the different species of plasmodia. The estivo-autumnal parasite, the most malignant of them all, remains lodged in the capillaries for at least thirty-six out of each forty-eight-hour period or cycle. During the time the parasites are lodged in the capillaries they are beyond the reach and effect of quinin in the blood-stream. Therefore it is necessary to keep quinin in the blood for a period of at least forty-eight hours and preferably seventy-two hours or three days. Thirty grains of quinin on each of three consecutive days always destroys all asexual plasmodia in the patient. There are no exceptions. Relapses result in some manner not now well understood from reproduction of sexual plasmodia or gametes, which are usually present in variable number. They reproduce in seven days and multiples of seven days, and give rise to the relapses occurring usually on the seventh, fourteenth, twenty-first and sometimes twenty-eighth days. Gametes are not killed by quinin or any other drug but their products of reproduction are killed by quinin. Thirty grains of quinin, once a week, for six weeks, will always sterilize the blood of all plasmodia after the asexual parasites have been destroyed by the first three days of quinin treatment. Continuous administration, especially of small doses of quinin, favor or increase the number of gametes and insure relapse or chronicity.

### Treatment of Pellagra

Dr. Seale Harris, Mobile, Ala.: In beginning the treatment of pellagra I usually give several small doses of calomel, 1/20 grain, every hour until ¼ grain is given, then bismuth subnitrate in doses of from ½ to 1 dram, with 5 grains of phenyl salicylate every two or four hours as may be necessary to control diarrhea. I have rarely found it necessary to use opium. When there is absence or deficiency of hydrochloric acid, dilute hydrochloric acid with pepsin often relieves the gastric symptoms and will not infrequently control diarrhea. Colonic irrigation with normal salt solution is often helpful. When there is stomatitis with ptyalism, potassium chlorate, given internally, yields splendid results. Mild antiseptic mouth washes, as diluted liquor antisepticus alkalinus, are helpful. Fowler's solution should be given in ascending doses of from 1 to 15 or even 20 drops, three times a day, or until the physiologic effects are obtained.

### Pathology of the Heart in Rheumatic Infection in Children

Dr. W. W. Harper, Selma, Ala.: In children endocarditis is often the only symptom of rheumatism. A primary attack of rheumatic endocarditis is not ulcerative, but usually leaves the heart-valves in such a condition that vegetations frequently develop during a second attack of rheumatism. Such valves are especially vulnerable should the patient be attacked subsequently by any of the pus-producing bacteria, such as the pneumococcus, streptococcus or colon bacillus.

### Central Cirrhosis of the Liver

Dr. V. H. Bassett, Savannah, Ga.: I had a case of central cirrhosis of the liver with acute endocarditis of gonorrheal origin in a man aged 22, following an acute attack of specific urethritis. The symptoms were fever with delirium, dyspnea, hemoptysis, icterus and generalized edema. The course of the disease was about eight weeks. At necropsy an acute ulcerative and vegetative endocarditis of the mitral valve, with a stenosis, was found, with hypertrophy and dilatation of the right side of the heart. The lungs showed the changes of chronic passive congestion. The liver did not resemble a nutmeg liver, but differed from a normal liver only in being somewhat cloudy, paler and somewhate firmer in consistency. The condition of fibrosis of the centers of the lobules was not suspected from the anatomic condition, but was found on making microscopic sections of the liver. The fibrosis was diffuse, affecting the centers of practically all the lobules, and occupied a space of a round or oval character, about equal in width to one-fourth of the radius of the lobule. The connective tissue was young and there was little pigmentation or other evidence of a previous chronic passive congestion of any extent.

Dr. W. A. Dearman, Long Beach, Miss.: I collected from a bed which a pellagrin had occupied for six months, a large number of bedbugs. I induced these bedbugs to bite and abstract blood from the large vein underneath the wing of a full-grown chicken. After a few minutes they were removed to a test-tube. This process was repeated at intervals of every other day for about three weeks; many of the bugs by this time were dead. Up to this time (a period of about four months) no lesions have developed in this chicken. On several occasions my attention was attracted by the malignancy of certain cases of pellagra in persons in whose premises were found mangy dogs, heavily infested with fleas, (*Ctenocephalus serraticeps*). These dogs were in the habit of sleeping on the beds in the daytime. One of these patients, a negro woman, gave a history of having been heavily infested with fleas from this dog, and had noticed no signs of her pellagrous condition until she had come in possession of the dog. I placed the dog in a cage with a full-grown rhesus monkey and kept them continuously associated for thirty-seven days. The monkey soon became heavily infested with fleas from this dog, as they could be seen crawling on her body and buried in the skin. The dog died from emaciation and a black diarrhea. After three months no signs of pellagra have developed in the monkey.

I feel inclined to doubt that the cause of the disease is lurking in spoiled corn. I believe that pellagra is in all probability an insect-borne disease, and the dog- and cat-flea should be looked on with suspicion.

### The Abderhalden Test

Dr. William Krauss, Memphis, Tenn.: The causes of failure may be said to be the serum, the placenta, faulty dialyzing thimbles, old or improperly stored ninhydrin solution or faulty technic. I prefer Schwartz' plan of boiling 5 c.c. of the dialysate with 0.1 c.c. of ninhydrin. I use a marked wide test-tube and restore the bulk after boiling for one minute. There have been no failures either way in the two tests made since adopting my latest technic, but I expect to meet them with more experience. I think that inactivated serum is the best control.

### Tuberculosis

Dr. E. C. Thrash, Atlanta, Ga.: I believe that tuberculosis is as certainly an alimentary disease primarily as is typhoid.

My experience in handling large numbers of children of tuberculous parents has been that practically all of them have tuberculous adenitis, and are positive to the Moro and von Pirquet tests, showing that they have become infected from their parents. I rarely find one with lung involvement. Also most of the children on whom I have held a post-mortem examination have died of chronic wasting diseases due to disturbances of nutrition and have shown tuberculous infections in the lymph-nodes of the abdomen, with normal lungs.

### Distinction between an Infection by Tubercle Bacilli and Tuberculosis

Dr. Mary E. Lapham, Highlands, N. C.: Tuberculosis enters every home. All children are infected before maturity. It is impossible to avoid the infection. Children should be examined by experts in order to detect the first changes before harm has been done. Tuberculosis in well persons is the most dangerous because it is never suspected. All animals have tuberculosis because the bacilli are universally present in their food. Four hundred thousand children in the United States are infected with tubercle bacilli from the milk of cows. It is not enough to protect a child from exposure to contagion. The infection by tubercle bacilli is not prevented by quarantine or segregation. The development of this inevitable infection must be arrested by its prompt detection. This can be assured only by regular examinations by competent experts. The prevention of tuberculosis can never be accomplished by obliteration. Detection and no delayed diagnoses are our surest safeguards.

### Protection for the Postsanatorium Tuberculous Patient

Dr. L. B. Morse, Hendersonville, N. C.: I wish to lay down some general rules for the guidance of ex-sanatorium patients: Place yourself under the care of a good physician. Approximate the sanatorium life closely, particularly in the beginning. Rest in bed for one week. Increase exercise (walking) with exceeding care both as to time and to distance, and note results. Take the precaution to "rest before getting tired." Make regular hours a conscientious habit, both as to rest, exercise, meals and sleep. Keep away from every sort of amusement and entertainment until thoroughly cured. Reduce visiting to a minimum. Maintain, if possible, a good body-weight. Be scrupulously particular regarding the morning bowel movement. With increasing strength, exercise an increasing pride in the maintenance of a good bodily posture. Taboo all dissipation. Protect yourself if possible from all worry and strain. Do not remain in the same room with a patient suffering from any sort of acute inflammation of the nose or throat. Finally, remember always that the things that made you well, in the main, are the things that will keep you well.

### The Evolution of the Treatment of Ectopic Pregnancy

Dr. Stuart McGuire, Richmond, Va.: All surgeons agree that an operation should be done in a case of unruptured tubal pregnancy as soon as the diagnosis is made. There is a serious difference of opinion among the best surgeons as to when to operate in a case after rupture occurs. I favor an immediate operation, not only because it is in accord with general surgical principles, but also because I have seen the practice save apparently moribund patients. I am opposed to the removal of the opposite tube, unless it is clear that the tube is diseased. If by leaving it I have subjected some patients to a second operation that might have been avoided, I have with equal certainty made possible the birth of some babies that otherwise would not have come into existence.

### Ovariotomy Sub Partu

Dr. W. Kohlman, New Orleans: The important points in the treatment of these complications are: 1. Vaginal ovariotomy in small tumors without adhesions is to be followed by delivery by the natural passages. 2. Cesarean section and abdominal ovariotomy should be the operation of choice in all cases of solid tumors, cystic tumors, with probable adhesions, or intraligamentous development, or in all conditions in which a prolonged and difficult labor is suspected.

## AMERICAN

Titles marked with an asterisk (*) are abstracted below.

### American Journal of Diseases of Children, Chicago

*December, VI, No. 6, pp. 381-448*

1 *Duodenal Ulcers in Infancy. L. E. Holt, New York.
2 *Casein in Infant Feeding. H. I. Bowditch and A. W. Bosworth, Boston.
3 *Parotitis Complicated with Meningitis. G. N. Acker, Washington, D. C.
4 *Case of Congenital Cyst of Thyroid in Child Aged 1 Year, Producing Death by Asphyxiation. H. C. Clark, Ancon, C. Z., and A. G. Farmer, Gatun, C. Z.

1. **Duodenal Ulcers in Infancy.**—Regarding the treatment of this condition, Holt says: Medical treatment is to be symptomatic only, and surgical treatment is as yet inadvisable in most cases. He reports four fatal cases and reviews the literature.

2. **Casein in Infant Feeding.**—The authors claim that formulas with exact percentages of protein can be obtained by determining the percentage of casein in the creams and milks used, and further, that powdered dry casein and paracasein can be used in making up shortage of protein in place of fat-free or skim milk. This powdered dry casein or paracasein is very easily digested, and is capable of furnishing all the protein requirements of the growing baby.

3. **Parotitis Complicated with Meningitis.**—Acker cites two cases and reviews the literature briefly.

4. **Congenital Cyst of Thyroid in Child.**—During the past three and a half years, at the Board of Health laboratories, Ancon, 21 specimens of thyroid glands showing large colloid cysts associated with hemorrhages and fetal adenomata have been received from the surgical clinic of Ancon Hospital, and 4 similar cases have been found at necropsy during the same interval of time. Sixteen of them occurred in females and 9 in males. Thirteen of these cases were in Americans, all but one being females. Seven were in male Spaniards, one instance in a male Panamanian and one in a male Greek. Only 3 of the 26 cases occurred in negroes: 2 female Jamaicans and a female Barbadian. The ages ranged from 19 to 61 years, the average being about 38 years. A fair idea of race incidence at Ancon Hospital may be had from a recent analysis of 1.500 successive necropsies in which 1,088 were West Indian negroes, 230 Spanish-Indian mixture, 108 Spaniards, 25 Americans, the other 49 being divided among the various countries of the old world. Thus, the authors state, one may form an idea as to the relative frequency of thyroid disease among the Spaniards and Americans and the low percentage in the black race.

5. **Thyroid in Exophthalmic Goiter.**—A detailed pathologic study by Wilson of fixed tissue preparations from 1,208 thyroids, removed from patients whose condition would ordinarily have been diagnosticated exophthalmic goiter, showed that 79

per cent. of the thyroids contained large areas of marked primary hypertrophy and hyperplasia. A parallel clinical study has shown that for a period of three years all patients with true exophthalmic goiter, and from whom gland tissue was removed, fall into this list. In the series of 1,208 so-called "exophthalmic goiters" plus 585 so-called "simple goiters," or a total of 1,793 thyroids, but four instances of marked primary hypertrophy and hyperplasia of the parenchyma have been noted in cases which did not show clinical symptoms of true exophthalmic goiter. Three of these four patients were children. Twenty-one per cent. of the 1,208 glands studied were either regenerations or adenomas. Clinically, while all of these were markedly toxic, all were chronic and none of them would now be grouped clinically as true exophthalmic goiter. By assuming that the symptoms of true exophthalmic goiter are the results of an excretion from the thyroid, and by attempting to determine the amount of such excretion from the pathologic data, Wilson says one is able to estimate in a large series of cases the clinical stage of the disease with about 80 per cent. of accuracy and the clinical severity of the disease with about 75 per cent. of accuracy. It would therefore appear that the relationship of primary hypertrophy and hyperplasia of the parenchyma of the thyroid to true exophthalmic goiter, is as direct and as constant as is primary inflammation of the kidney to the symptoms of true Bright's disease. Any considerable finding to the contrary Wilson believes to indicate either inaccurate or incomplete observations on the part of the pathologist or clinician, or both.

6. **Exophthalmic Goiter.**—Of 2,917 cases coming to operation between Jan. 1, 1909, and Jan. 1, 1913, and analyzed by Plummer, 42.8 per cent. were hyperplastic and 57.2 per cent. were non-hyperplastic. Of the hyperplastic 99.2 per cent. were toxic and 0.8 per cent. were atoxic. Of the non-hyperplastic 23.3 per cent. were toxic and 76.7 per cent. were atoxic. Patients coming under observation with non-hyperplastic toxic goiter gave a history of having first noted the goiter at the average age of 22 years, and the evidence of intoxication at the average of 36.5 years: The corresponding ages for hyperplastic goiter were respectively 32 and 32.9 years.

Throughout the series the number of cases in which the clinician failed definitely to note and attribute constitutional symptoms to the thyroid and which were later diagnosed by the pathologists hyperplastic thyroid, varied from two cases in 1909 to four cases in 1912. The pathologic reports failed to show the presence of hyperplasia in the cases in which exophthalmos was noted by the clinician six times in 1909, four times in 1910, twice in 1911, and not in a single instance in 1912. As to whether the symptom-complex accompanying hyperplastic goiter is to be directly attributed to disturbed thyroid function, Plummer says that while he has so considered it in his paper only as a matter of convenience for pointing out the association of the clinical and pathologic findings, he calls attention to a point in support of this theory that, so far as he knows, has not hitherto been made, namely, that an individual, aged 22 years, with an adenoma of the thyroid, has a definite chance of developing a train of symptoms during the thirty-sixth year so similar to the symptom-complex associated with hyperplastic thyroid, that the best-trained diagnosticians are constantly confusing the two conditions. He does not believe that the symptom-complex of non-hyperplastic toxic goiter can be associated with any definite pathologic change in the thyroid.

The order of onset of the most important symptoms of exophthalmic goiter based on the average of the Mayo series was as follows: (1) cerebral stimulation; (2) vasomotor disturbances of the skin; (3) tremor; (4) mental irritability; (5) tachycardia; (6) loss of strength; (7) cardiac insufficiency; (8) exophthalmos; (9) diarrhea; (10) vomiting; (11) mental depression; (12) jaundice, and (13) death.

7. **Depressor Substance in Serum of Blood of Patients with Exophthalmic Goiter.**—The serums from twenty-eight patients having exophthalmic goiter were used by Blackford and Sanford. Other serums examined included those from normal individuals, from patients having goiters without apparent intoxication, and from patients presenting the picture of a long-standing intoxication, presumably due to adenomas of the thyroid. Only the serums from patients with active symptoms of exophthalmic goiter and with markedly hyperplastic glands, as shown by microscopic examination, produced in the dogs injected any definite symptoms of cardiovascular depression.

The results of these experiments convince the authors that fresh extracts made from exophthalmic thyroids contain a powerful depressor substance. A powerful depressor substance likewise exists in the serums obtained from certain cases of exophthalmic goiter. The latter substance is present in direct proportion to the clinical acuteness and severity of the disease. The serums from patients with non-hyperplastic thyroids do not have a depressor action. After an active depressor dose of the serum from a case of exophthalmic goiter the depressor action of the extract of an exophthalmic goiter is weakened or abolished. The converse is also true.

12. **Gaucher's Disease.**—Brill and Mandlebaum believe that the disease starts simultaneously in the spleen, bone-marrow and lymph-nodes. In the last, however, it may appear somewhat later or be slower in development, an assumption which finds its support in the fact that they have found in a very early case, a child aged 4½ years, the process in some of the nodes to be far less advanced than in the spleen and marrow.

19. **Recurrent Anterior Dislocation of Shoulder.**—Young first locates the pectoralis major muscle. A grooved director is placed beneath this muscle and its lower portion divided. The long tendon of the biceps may be displaced inward, and the broad flat tendon of the latissimus dorsi can be hooked up by the finger, or by some blunt instrument, such as an Allis' dissector; the insertion of the tendon is exposed and the lower half divided. No attention is paid to the capsular ligament. The bicipital groove was exposed by an incision over the space between the deltoid and pectoralis major muscles, and the cephalic vein was displaced outward. The pectoralis major and the deltoid muscles were brought together with deep catgut sutures. The skin was closed with a continuous suture and the arm dressed in an extended position on a triangular splint and kept in that position for a period of two weeks. Following the operation, and on the recovery of the patient, there was no loss of power over this shoulder as compared with its fellow, nor has there been a recurrence, although the man has again resumed his occupation and has taken part in several games of soccer since.

25. **Treatment of Fractures.**—Fractures of the shaft of the humerus, says Jones, may be troublesome from two causes—either on account of damage to the musculospiral nerve

through injury or inclusion in callus, or due to non-union, the latter being generally caused by inefficient fixation. Many cases of supposed permanent damage to the musculospiral nerve are cured in a few weeks by application of a splint which holds the wrist in dorsiflexion. The patient generally goes about from the beginning of treatment. There is not room for the thick splint frequently employed to lie comfortably in the axilla between the patient's arm and the body, and hence the arm is not as firmly fixed as it should be. Sheet-metal splints occupy very little space. The best method in Jones' opinion, of setting these fractures, especially when working single-handed, is the following: First get ready three sheet-metal splints. The external one extends from the external condyle to well above the shoulder and its upper end is bent over to form a sort of shoulder cap. A short splint extends from above the internal condyle to the anterior fold of the axilla, and a similar posterior one to the posterior fold of the axilla. Flex the elbow to an angle of about 60 degrees and sling the wrist to the neck, with the patient sitting in a chair. A loop of bandage is put around the flexure of the elbow and does not reach the floor. By putting one foot in this loop, the surgeon can apply as much extension as he chooses, while both hands are free to manipulate the fractured ends into correct position. The splints are applied and squeezed up till they fit closely around the arm. A turn of sticking plaster now binds them into a cylinder fitting the arm. A sheet of wadding is then placed between the arm and the chest. The whole is secured with a broad bandage carried over the shoulder and the part of the external splint which is turned over like a shoulder cap. This prevents shortening, for the lower end of the cylinder fits around the arm above the condyles. As the whole arm is in a close-fitting cylinder, displacement cannot easily take place, and the patient is quite comfortable. Except to free the musculospiral nerve from callus, operation is rarely necessary, for even if there is some overriding of fragments a little shortening of the arm does not give rise to any serious impairment of function to the ordinary man. All fractures through the condyles and indeed all fractures about the elbow, except fracture of the olecranon, are best treated in the fully flexed position. For the first few days the forearm, fully supinated, should be bandaged to the upper arm in fullest flexion; after this it is sufficient to keep the wrist slung short up under the chin.

34. **Treatment of Leukemia with Benzol.**—In the case cited by Barker the course of benzol administration extended over approximately eleven weeks during which period the total number of white blood-cells returned to normal, the red blood-cells increased from 3,600,000 to 5,000,000, the hemoglobin changed from 65 per cent. to 82 per cent., and the patient's general condition showed definite improvement. In as far as he can judge of this new line of therapy in leukemia from the observation of the case reported, Barker shares the belief of most authors as to its efficacy in reducing the white blood-cells, and in leading to an associated subjective improvement of the patients. His patient progressed in a satisfactory manner with the exhibition of benzol alone, but he feels that the possible value of other accessory measures, such as Roentgen rays, arsenic, thorium-X and radium in the therapy of leukemia should be kept in mind. The ultimate place of benzol in the treatment of leukemia, polycythemia and Hodgkin's disease can be determined only through further studies which include careful clinical observations. Barker emphasizes the facts, first, that benzol does possess dangerous toxic properties; second, that its clinical effects are not yet clearly understood, and, third, that the greatest care should be exercised in its administration. A studious regard for the dosage as thus far determined, a watchfulness for the manifestations of poisoning that are well defined and easily detected, and a willingness to employ other measures in conjunction with this drug, in Barker's opinion, are means that will serve to give the new treatment a fair trial and prevent its falling into an undeserved disrepute. Certainly, no patient should be treated by benzol unless he can be kept under continuous close observation; for the present, therefore, it may be well to restrict its use to the treatment of patients in hospitals, rather than to run the risks attendant on its extension to domiciliary practice.

35. **Bence-Jones Proteinuria in Leukemia.**—So far as Boggs and Guthrie have been able to ascertain, three of their cases are the first reported instances of Bence-Jones proteinuria in association with myeloid leukemia. It has never been observed in the acute forms of the disease, either lymphatic or myeloid, and, including the cases presented here, only eight times in the chronic varieties. The Bence-Jones protein alone was present in two cases, while Möner's body also was present in the other two cases, as well as serum albumin in one case. The excretion of the Bence-Jones body was small in amount, which seems to be characteristic when it occurs apart from multiple myeloma. The chlorid output was normal in one case, which is markedly different from the condition found in two other cases and in cases of myelomatosis and carcinomatosis. In two cases the effect of the benzol treatment is especially noteworthy, in that a marked reduction or eventual disappearance of the proteinuria and its associated polyuria, occurred, parallel to the diminution in the leukocytosis and apparent approach of the bone marrow to a more nearly normal condition. These cases furnish additional confirmation of the previously expressed view, that Bence-Jones proteinuria is not essentially dependent on one disease, but is a manifestation of disturbances in the bone marrow affecting endogenous metabolism.

37. **Tests for Hepatic Function.** — A consideration of the extrahepatic factors involved in the sugar regulating metabolism, the influence of the glands of internal secretion and of the vegetative nervous system, the ability of other tissues than the liver to handle sugar, and the ability of the uninjured liver substance to compensate in disease leads the authors to say that the sugars are theoretically unsatisfactory as tests for hepatic insufficiency. There are a series of great practical difficulties in applying the tests; namely, nausea, vomiting and diarrhea after feeding, faulty absorption, intestinal fermentation, portal obstruction with collateral circulation, retention of sugars in nephritis, and inconstancy in the diet. There are serious objections to the methods as they have been applied; namely, the use of arbitrary amounts of sugar, and the use of a definite standard of excretion. An analysis of the reports show their significance to be lessened owing to confusion in the conception of hepatic insufficiency, insufficient clinical data and neglect of the practical considerations mentioned.

38. **Idem.**—Hurwitz and Bloomfield are convinced that there is experimental evidence to show that in the intestinal tract of dogs lactose is split into its constituent molecules—dextrose and galactose—and that after feeding lactose to dogs, galactose is excreted in the urine. Studies by various workers show that when lactose is split, the liver can form glycogen from galactose, but to a more limited extent and with greater difficulty than from the other monosaccharids. The experi-

ments cited by the authors show that it is more accurate to determine the tolerance of an animal before producing a liver injury than to accept arbitrary standards of normal tolerance, expressed either in total number of grams or in grams per kilogram of body weight. Whereas the normal tolerance of dogs for lactose expressed in grams per kilogram of body weight is fairly constant, the total number of grams tolerated by different animals shows wide variations. Eck fistula dogs show a reduced tolerance for lactose, which, however, may result from flooding of the systemic circulation with sugar rather than from liver injury. In susceptible animals, central necrosis produced by chloroform poisoning results in the reduction of the lactose tolerance by 50 per cent. or more. In one animal with chronic passive congestion of the liver, no reduction in the lactose tolerance could be demonstrated.

60 *Stenosis of Cervix Uterus: Treatment by New Method. J. D. Matthews, Detroit.

55. **Endocarditis.**—Babcock emphasizes the fact that there must exist some focus of infection from which streptococci may gain access to the lymph-stream and blood. Such a focus may exist in the appendix, gall-bladder, intestine or any other closed cavity, but without doubt the most frequent atrium of infection is the tonsil, and the viridans streptococcus has been obtained from an inflamed tonsil at the height of articular rheumatism. Furthermore, by cultural methods *Streptococcus hemolyticus* has been converted into the *Streptococcus viridans*, and the latter into the pneumococcus. The human body is capable of transforming the *Streptococcus hemolyticus* into the *Streptococcus viridans*, so that a child with chronically infected tonsils may get an acute endocarditis or the far more terrible form caused by the viridans organism. Consequently, whenever a victim of valvular disease, particularly of aortic regurgitation, has tonsils that have been inflamed and are no longer healthy, Babcock says they should be extirpated, and he emphasizes the fact that tonsillectomy in a child with valvular disease is safer under ether and by a rapid, skilled operator than if the patient is left to the risk of streptococcus infection from the tonsils left *in situ*. In other words, the risk of this operation is less than is the danger of subsequent ulcerative endocarditis. Chronically diseased tonsils are not always enlarged, nor are they always red, for even small buried tonsils may and often do contain in their center a pocket of pus.

That malignant endocarditis due to the *Streptococcus viridans* is most often the sequel of a throat infection has been impressed on Babcock by the frequency with which he gets a history of the ill-health having begun as a so-called "attack of the grippe." Autogenous vaccines by assisting the system to destroy circulating bacteria may lessen the intensity of the symptoms and may even retard but cannot reach the organisms imbedded in the vegetations and protected by a covering of fibrin. Consequently our aim should be the prevention of this frightful malady, and since the preponderance of evidence is in favor of diseased tonsils as the atrium of infection it should be our duty to so inform patients with valvular lesions. The complete enucleation of the tonsils may not be a guarantee against future endocarditis of this viridans type, but it is a safeguard and hence should be resorted to whenever an individual having once suffered from endocarditis is subject to recurrences of tonsillar inflammation or has tonsils that are no longer healthy and capable of performing their normal function.

60. **Stenosis of Cervix Uteri.**—After proper dilatation Mathews seizes the anterior lip of the cervix with a volsellum forceps; the lateral borders are grasped by tenaculum forceps; a straight scissors is used in dividing the posterior, or under lip, to the internal os. A curved needle with a silk or No. 1 catgut is introduced, catching the mucous coat and brought through, taking up the mucous coat posteriorly; the ligature is tied. The same procedure takes place on the two lateral surfaces of the wound. The vagina is packed with sterile gauze which is left in position twenty-four hours. The patient is placed in bed for ten days, after which she is allowed to return to her home.

67. **Device for Treating Fractures.**—The device used by Parham and Martin—a band from 1 to ⅜ of an inch in width, 6 inches long, with a slit in one end and a small hole in the other—is passed around the bone quite easily by bending to a suitable angle; this is readily accomplished, as the bands are made of malleable iron. The free end is then inserted through the slot in the instrument, made fast to the pin on the screw lever, and with it sufficient force is exerted to make it fit snugly around any unevenness of the bones. It is fixed in position by slightly relaxing the screw as the instrument

is turned back over the slit, and is cut to any desired length by holding between the blades of a strong pair of scissors or bone-cutters and worked to and fro several times. The cut end is then pressed down and the band remains fixed.

88 Cancer. J. A. Guthrie, Portsmouth, Va.

82. **Oil-Ether Anesthesia.**—The mixture used by Gwathmey for adults (2 ounces of olive oil and 6 ounces of ether) is given with the patient in bed on the left side, in the Sim's position, a convenient lifter having previously been placed under him. A small catheter, well lubricated, is inserted 3 to 4 inches within the rectum; to this catheter a funnel is attached. The mixture should be poured slowly into the funnel, at least five minutes being consumed in administering 8 ounces, the usual amount required. It is best not to withdraw the tube immediately, but to wait until the patient is partly unconscious and the muscles are relaxed. From five to twenty minutes (according to the percentage used) should be allowed for the anesthetic to take effect, before the patient is moved. The patient should then be lifted gently on a stretcher and carried to the operating room. The anesthetist at this time should see that a clear airway is maintained when necessary, by placing a finger under the symphysis of the lower jaw. If the patient shows sign of approaching cyanosis, loss of lid reflex, stertor, or embarrassed respiration of any kind, two or three ounces of the mixture should be withdrawn by a small rectal tube placed 4 to 6 inches up the rectum. If the breathing is easy and regular, with the reflexes active, the patient will be found to be relaxed and in surgical narcosis as far as the operation is concerned. At the end of the operation, two small rectal tubes should be placed in position, as high up the colon as convenient without traumatism, and cold water soapsuds injected into one tube and drawn off through the other; 2 to 4 ounces of olive oil should then be introduced into the rectum and the tubes withdrawn. The patient should be gently returned to bed, with as little jolting or handling as possible, the room should be darkened, and free ventilation secured. For children under 6 years of age, a 50 per cent. solution should be employed, allowing 1 ounce of the mixture for every 20 pounds of body weight. For patients from 6 to 12 years of age, use a 55 to 65 per cent. solution, without preliminary medication, keeping the patient quiet, and allowing twenty to thirty minutes for the full effect. Allow 1 ounce for every 20 pounds of body weight, as before.

For patients from 12 to 15 years of age, use the same percentages and amounts, with possibly the addition of 1/12 grain of morphin and 1/200 of a grain of atropin given hypodermically as a preliminary.

From 15 years upward, a 75 per cent. mixture is employed, the amount and preliminary medication varying with the size and general condition of the patient and the same rule being followed as to quantity, that is, 1 ounce for every 20 pounds of body weight. For an adult weighing about 160 pounds 8 ounces would be required. This represents the usual dose for the average patient.

1. **Treatment of Syphilis in Early Stages.**—The authors sum up their views as follows: 1. Commence treatment in the early primary stage whenever possible. 2. Destroy the primary sore whenever possible and insist on the patient receiving not less than three salvarsan and ten mercurial injections. 3. On no account neglect subsequent observation, and prescribe a definite course which is just as strenuous as in the first instance if the patient shows the least sign, clinical or Wassermann, that his disease has not been eradicated. 4. Be cautious about pronouncing a patient cured in any case, but certainly do not do so till he has continued free from all signs, clinical or Wassermann, for at least a year after suspension of treatment in primary cases, and two years in secondary cases.

8. **Hyperthyroidism.**—Eleven cats were fed by Farrant on thyroid powder, a 2½ per cent. solution of purified thyroid, previously digested thyroid, and previously boiled thyroid. The doses given were from 1 to 3 grams per day. The effect of the thyroid feeding produced but little change during the first three days. On about the fourth day the animals became suddenly weak and went off their legs; this stage of weakness passed off in about forty-eight hours, but then toxic symptoms set in and slowly progressed until the animals became moribund. Some of the cats appeared for a time to come to a standstill, but they eventually succumbed.

In four the feeding was stopped when they became moribund, as they were required for other purposes. The hairs came out and the fur became unkempt; when the animals died the fur was very thin. There was a gradual loss of body weight from 28 to 53 per cent. Muscular weakness corresponded to the loss of weight. In two cats in which the thyroid feeding was stopped and which were allowed to recover, a steady increase of weight followed. Salivation took place during the later stages of the experiments; its intensity varied with different cats; at the last it was represented by a thick ropy mass hanging from the mouth. The appetite was much increased though occasionally they would refuse all food for two or three days at a time. Diarrhea constantly occurred even in the cat subjected to subcutaneous injections. The urine reduced Fehling in some of the cats, but not in others. The daily records made with the polygraph showed that the pulse-rate steadily increased. The highest was 384. The heart's impulse appeared to be diffused over a larger area of the thorax than previously. The rates steadily diminished in the two cats in which the thyroid feeding was stopped. There was no prominence of the eye that could be compared to that seen in exophthalmic goiter. The cats became tremulous, and the hair could be seen to shake, but it was quite impossible to differentiate this from the effects of the general weakness and rapidity of the heart's action. It cannot be compared to the tremor of exophthalmic goiter. The cats during the experiments became quite tame, and purred on being handled; in the later stages they appeared to start at a sudden noise.

At the necropsy there was almost entire absence of fat; the muscles were extremely wasted. The intestinal mucous membrane showed hemorrhagic changes, but not invariably. The intestinal contents were conspicuous by the absence of worms, which are generally present in large numbers in normal cats. The mesenteric lymph-nodes were sometimes enlarged, but not more so than is commonly seen in cats, so that no comparison can be made with the lymphoid changes seen in exophthalmic goiter.

Nineteen rabbits were fed on thyroid in milk in doses varying from 0.2 to 1 gram daily. They rapidly lost weight and died, except five in which the experiments were not pushed to their termination. Death occurred from the fifth to the nineteenth day with one exception; this one survived twenty-eight days. The fur became unkempt and fell out. The loss of weight varied from 19 to 42 per cent. of their total body weight. The appetite was much increased, and they ate ravenously right up to the time of their death. Diarrhea was a constant symptom, but no salivation was noted. The urine was not tested or estimated. The pulse-rate steadily increased, the highest recorded being 420 per minute. No exophthalmos or constant alteration in the nictitating membrane was noticed. The rabbits became weak and tremulous, but no comparison can be made between this and the tremor of exophthalmic goiter. Three of the five rabbits in which the experiment was not pushed to a termination died suddenly while being given ether as an anesthetic.

Fifteen guinea-pigs were fed on thyroid daily, from 0.2 to 0.6 gram. The fur changes, loss of weight, diarrhea and increased appetite that occurred agreed with the changes seen in the rabbit; the naked eye pathology was also similar.

Twelve dormice were fed on 0.025 gram of thyroid a day, twelve others were used as controls. Beyond falling out of the fur, diarrhea and loss of weight, no changes were to be noted. They died in four to nine days, having lost 13 to 38 per cent. of their weight. The thymus was found diminished; in some at the time of death it was quite small, and no fat was to be seen in it, while others died before all the fat had disappeared.

The cats proved the most resistant, the other three were very susceptible; the rabbits lived longer than the guinea-pigs; this one would expect from their size. The cardinal symptoms in all were fur changes, loss of weight, weakness, increased appetite and diarrhea. Tachycardia was well marked in the cats and rabbits, but no reliable observations could be made in either the guinea-pigs or the dormice, owing to the difficulties involved in their small size.

### Lancet, London

*November 22, II, No. 4708, pp. 1448-1516*

14 Origin and Growth of Royal College of Surgeons of England. R. J. Godlee.
15 *Some Requirements for Modern Clinical Teaching. D. Duckworth.
16 Treatment of Neurasthenia. J. S. R. Russell.
17 *Four Cases of Ureteral Calculus. H. Collinson.
18 *Primary Cause of Rheumatoid Arthritis. H. W. Crowe.
19 Case of Tumor of Pituitary Body. A. L. Taylor.

15. **Requirements for Clinical Teaching.**—A clinical teacher, says Duckworth, has great responsibilities. Before all things he must be human and sympathetic, never forgetting that he is dealing with patients who have souls as well as bodies, and not with mere "cases." He has to illustrate and teach good manners as well as medicine. He must believe in his art, for a sceptic in therapeutics can teach nothing. He should not pursue many novelties, for in Duckworth's experience novelty-hunters have not been well instructed in the principles of medicine in their early career. To these requirements Duckworth adds a large measure of tact and common sense, no small amount of geniality and humility, and a due degree of such dignity as rightly belongs to men charged with serious duties to their country and their fellow creatures.

17. **Four Cases of Ureteral Calculus.**—The cases cited by Collinson are as follows: 1. Calculus impacted in the upper end of the ureter; calculous anuria; nephrotomy. 2. Calculous cast occupying the whole length of the ureter; nephrectomy and ureterectomy. 3. Calculus impacted in the iliac portion of the ureter. 4. Calculus impacted in the juxtavesical portion of the ureter; retroperitoneal ureterotomy.

18. **Primary Cause of Rheumatoid Arthritis.**—Crowe describes rheumatoid arthritis as a disease caused primarily by a common inhabitant of the skin, the *Micrococcus epidermidis*, variety deformans, or more shortly, the *Micrococcus deformans*, and suggests that the germ produces the disorder mainly by its action on some portion of the nervous system, and that other pathogenic germs are frequently actively engaged as a secondary mixed infection.

In 26 cases of typical rheumatoid arthritis the organism was present in all. It was cultured in 22 and positive complement-fixation was demonstrated in the remaining 4. In a further 14 less severe and doubtful cases of rheumatoid arthritis, the organism occurred in 11, being cultured from 9. If neuritis is included the total number of cases becomes 48, and the incidence 45—that is to say, 93.75 per cent. Streptococci were present in addition to the *M. deformans* in 21 cases and *B. coli* in 7. Crowe has found the *M. deformans* in the urine in two or three cases of mild septicemia, occasionally in neurasthenia, and also in rheumatism; among 35 of such cases recently investigated it has appeared 13 times.

*November 12, No. 92, pp. 917-928*

25 Intestinal Bacteria and Auto-Intoxication. H. Roger.
26 *Local Prophylactic Treatment of Furunculosis. P. Gallois.

23. **Cure of Experimental Tetanus.**—Ruffer and Crendiropoulo started a series of experiments to determine the reason why certain serums and antitoxins, while having a preventive action against the microbe in question, have no therapeutic action after symptoms due to the microbe have developed. They are experimenting with tetanus germs and serum and their work to date has already demonstrated, they say, that different substances develop in the muscles of tetanized animals some of which favor the effects of the tetanus toxin while others check the toxic action. Antitetanus serum is

incomplete; it lacks something to render it truly effectual and this lacking substance, they assert, can be procured from the muscles of tetanized animals. Guinea-pigs treated on this principle recovered from the experimental tetanus.

26. **Prophylactic Treatment of Furunculosis.**—Gallois denounces the use of water when there are pimples and boils, saying that moist dressings maintain and perpetuate the infectious process. He scrubs the region with soap as this has an antiseptic action while it removes the old epidermis in which germs are lurking, and opens up the clogged outlets to the glands in the skin. Then he rinses the region with an antiseptic, phenol 1 to 40, or hydrogen dioxid, and with blunt scissors snips the top of all the pustules and pimples and cauterizes the bottom of the little ulcer with a mixture of 2 gm. metallic iodin in 5 gm. acetone, applied on a toothpick swab. He is very careful not to squeeze any pimples or pustule, and he never lets his fingers touch the skin or, if he does, he sterilizes them anew before proceeding. He uses a square of lint or cotton to cover the region, spreading first on the cotton a thick layer of glycerite of starch with 10 per cent. boric acid. The dressing is renewed once or twice a day. The glycerin dehydrates the region and is thus practically a dry dressing. With this treatment the tendency to formation of furuncles dies out and by the end of a week or two the cure is complete. The last stage of the treatment consists in dusting the region with a dry powder, 20 parts talcum with 2 parts each of bismuth and paraffin; the latter makes the powder stick to the skin better. The patient is warned not to wear the clothes he wore before the treatment began, and the edges of collars, etc., are softened to prevent irritation of the skin liable to bring on new trouble. The treatment is thus a series of minute precautions bearing all toward the same goal—to prevent reinfection. Gallois insists on applying the dressing himself each time. Vaccination and internal measures may be useful, but they must not divert the attention from the main point in treatment, the local prophylaxis.

## Revue de Gynécologie, Paris

*November, XXI, No. 5, pp. 353-448*

27 The Transverse Abdominal Incision in Gynecology. O. J. Rapin.
28 *Treatment of Retrodisplacement of Uterus by Transplanting the Round Ligaments. J. M. Caballero.

28. **Treatment of Retrodisplacement of the Uterus.**—The tip of the kinked round ligament is sutured to the fascia of the rectus after being brought up through a tunnel parallel with the farther end of each tube. By this means the ligaments form a long flat ellipse instead of the narrow triangle of other technics. Caballero has applied this technic in 350 cases and extols its numerous advantages. The uterus is left freely movable and there is no disturbance with a later pregnancy. The direction of the uterus in respect to the axis of the pelvis is not altered.

## Semaine Médicale, Paris

*November 12, XXXIII, No. 46, pp. 541-552*

29 *Spasmodic Contraction of the Stomach. (Le gastrospasme.) L. Cheinisse.

*November 19, No. 47, pp. 553-564*

30 *Living Craniopagus. (Emi-Lisa Stoll.) M. Baudouin.

29. **Spasmodic Contraction of the Stomach.**—Cheinisse concludes his study of gastrospasm with the statement that atropin aids in differentiation; roentgenoscopy shows the spasm relaxing under the influence of the drug while the nausea and vomiting subside. It is useful consequently in treatment, and Cheinisse has found its action enhanced by giving cannabis indica with it. The cause should be treated, of course, trying to cure the neurasthenia or other nervous affection responsible for the gastrospasm. If tobacco has to be given up, the weaning should be gradual. Waldvogel has reported a case in which on the sudden dropping of tobacco the gastrospasm was succeeded by atony of the stomach with much residue, and the condition persisted for several weeks.

30. **Living Craniopagus.**—Baudouin describes with an illustration a craniopagus twenty months old when exhibited at Ghent last summer. The twins are normally formed except where they are joined by the skull, the parietal bones blending together. An interesting feature of the case is the angle of 90 degrees at which the planes of the heads are turned. The brains seem to be distinct, as one of the twins can sleep while the other is awake. As invariably occurs with double monsters of this kind, Baudouin remarks, the twins are of the same sex and the color of eyes, hair, shape of ears, etc., are the same in each; they are not two beings but halves of one. He has found seven cases on record of a craniopagus surviving for a few days. Five date from 1703 to 1861. The others are L. Blanc's case (1893), girls, who survived for five months, and Kissinger's case (1908), boys, who died the sixth day after birth.

No attempt at operating on a craniopagus is on record, but Munster's (1495) famous metopagus (joined at the forehead) lived to be 10 years old, when one of the girls died and the other did not long survive the separation. Baudouin emphasizes the necessity for operating before the death of either child. This is the capital condition for success, and the Stoll craniopagus should be operated on before the legs become atrophied from lack of use. The law in France forbids a surgeon, however willing to pay the subject, from even proposing any operation whatever for the simple purpose of promoting the progress of operative science.

## Beiträge zur Klinik der Tuberkulose, Würzburg

*XXVIII, No. 3, pp. 351-512. Last indexed, Nov. 8, p. 1755*

31 *Rare Forms of Tuberculosis. (Die menschliche Tuberkulose in ihren selteneren Erscheinungsarten.) G. Goerdeler.
32 Diagnostic Importance of Inoculation of Animals with Pleuritic Effusion. F. Japhé.
33 *Air Embolism in the Eye. (Luftembolie im Auge.) Stargardt.
34 *Abderhalden's Serodiagnosis in Tuberculosis. (Untersuchungen mit dem Abderhaldenschen Dialysierverfahren bei Tuberkulösen.) F. Jessen.

31. **Rare Forms of Tuberculosis.**—Goerdeler reports seventy-two cases or necropsies showing a tuberculous affection in some unusual location, as he describes in detail in this article of 114 pages. In nine cases the lesion was in the lower or middle lobe of the lung in persons between 60 and 80 and in one infant. He has found only one case on record of a similar atypical tuberculous lesion in an infant's lung. In two other cases the tuberculous process was located in the gums; in five in the esophagus. Another patient was a boy with a tuberculous abscess in the parotid gland. In another case a woman of 29 had a lupus carcinoma in the right cheek and tuberculous tissue was found adjoining it. The cadaver of a man of 56 showed a perforated gastric ulcer with healed lesions in the lung. Among the 4,620 cadavers, tuberculous gastric ulceration was found in only two other cases and in both it was evidently secondary to pulmonary lesions. In only six cases in his total material was a primary intestinal tuberculous lesion discovered.

The liver was the seat of the tuberculous process in three cases; in one this was apparently the primary process. A tuberculous abscess was found in both liver and pancreas in another case, the patient a man of 74. There were no striking symptoms in this case and no fever, all the liver cases showing that tuberculous processes in this organ may develop without characteristic symptoms. In three cases the male urogenital apparatus seemed to be primarily affected, no older lesion being discovered at necropsy. The uterus was the seat of an isolated tuberculous process in a woman of 68; the symptoms suggested cancer. He encountered only one other case of primary tuberculosis of the uterus; the tubes are generally affected first. In the group of thirteen cases of tuberculous processes in the serous membranes, the patients were nearly all elderly; the possibility of a tuberculous affection should be borne in mind in case of effusion in a cavity in the elderly. An abnormal temperature curve should suggest that the disturbances cannot be ascribed to mere senile insufficiency of the cardiovascular apparatus. The adrenals were the seat of a tuberculous process in three cases, and none of them showed any signs of changes in the skin and mucosa suggesting Addison's disease, confirming anew the looseness of the connection between this and adrenal tuberculosis.

The thyroid was the seat of the tuberculous process in one case; the gland increased rapidly in size. suggesting malignant struma. The patient was a well-nourished woman of 42 and the thyroid was removed, the patient dying the next day. The first symptoms had been observed five months before, but the woman had kept at work until three days before the operation. Necropsy was not permitted. The spinal dura was the seat of a circumscribed tuberculous process found at necropsy of a man of 66. Nothing in the clinical course had suggested the true nature of the disturbances noted; they consisted merely of atrophy of the muscles in the legs, some disturbance in micturition and defecation, and in the gait. The temperature had shown slight evening rises for a few weeks, which should have suggested a possible tuberculous process. A connection between trauma and tuberculosis was evident in a few cases of a tuberculous process in bone or muscle in elderly men or women. Goerdeler calls attention to the fact that in these seventy-two cases of atypical localizations of tuberculosis all but four were in adults, and in over half the cases in persons over 60. With isolated tuberculosis of lymph-nodes, cancer had accompanied or preceded it in six cases. One lesson taught from the experiences reported is the diagnostic importance of even a slight rise in temperature, especially at evening. The various modes of spread of the infection are discussed and a few pages of bibliography appended.

33. **Air Embolism in the Eye.**—Stargardt induced air embolism in rabbits and monkeys and found that the fundus of the eye showed the presence of air in the artery almost at once. The characteristic findings are described. and examination of the fundus is suggested as a means for differentiating air embolism in puzzling cases of collapse.

34. **The Abderhalden Serum Test in Tuberculosis.**—Jessen states that the dialysis method of Abderhalden is uncommonly instructive in tuberculosis. not only differentiating the tuberculosis but pointing out the special organ involved. He tabulates the findings in 381 applications of the test.

35. **The Friedmann Method.**—[This article consists of clinical talks delivered at a meeting in the auditorium of the Second Medical Clinic in Berlin on Oct. 26. 1913, for the demonstration of results obtained with the Friedmann tuberculosis remedy. It will be noted that this was a Friedmann meeting. at which there was no critical discussion and no representation of opposing views ]

Schleich gives Friedmann the credit for discovering a harmless and not infective form of the tubercle bacillus which is derived from the turtle and is said to have a curative action against human tuberculosis. Living bacilli are injected, producing at the point of injection an infiltration which is assumed to be a depot from which antigens are slowly supplied to the circulation. In certain cases the living bacilli are injected intravenously directly into the blood. Schleich presented ten cases of surgical tuberculosis and two of pulmonary tuberculosis which had improved greatly under the treatment. Two were cases of tuberculous testicle. one of which Professor Moeller is said to have declared could not be cured by tuberculin. He showed one case of florid phthisis together with suppurating cervical glands and an affection of the hip in which complete recovery had taken place. This patient had been treated for four years, showing the complete harmlessness of the remedy. The other cases were mostly examples of healed tuberculosis of the joints and bones in which the Friedmann remedy had been used.

Two cases of pulmonary tuberculosis were presented. The condition of the first on admission was shown by a roentgenogram, indicating. according to Schleich's interpretation, a complete destruction of one lung and extensive infiltration of the other. The patient was present in person and Schleich stated that she was really much better. The second patient was allowed to tell his own story. He reported remarkable improvement in spite of the extremely unfavorable prognosis which had been made by the physician who had treated him.

E. Müller presented eighteen cases selected so as to show the action of the remedy best. He is not inclined to modify the favorable opinion which he expressed in November, 1912. If the indications given by Friedmann are strictly adhered to, the remedy, in his opinion, will be found to be not only harmless, but very beneficial.

H. Thalheim summarized his experience in the following propositions: 1. Under all circumstances I secure with Friedmann's remedy a cessation of the toxic activity of the bacilli and of the specific symptoms. 2. I secure an early improvement in objective signs, especially an abatement of the râles, while the bronchitic and peribronchitic symptoms may not cease, as generally all cicatricial processes which pertain to healing even in favorable cases cause the persistence of auscultatory and percussory signs. 3. I secure a complete transformation of the constitution in the sense of full immunity, i. e., a restoration of the ability to work and complete feeling of health, such as no treatment hitherto has so permanently and so surely produced. 4. Previous treatment with tuberculin in many cases renders a cure more difficult. 5. Under all circumstances I regard increase of weight (without extra feeding), a permanent subjective feeling of well-being and ability to work as of more importance than the remains of a previously active focus as determined by auscultation and percussion.

Thalheim lays special stress on the importance of not making a second injection until the infiltration produced by the first has disappeared. He reports seventeen cases.

Immelmann discussed the evidence of tuberculosis of bones and of the lungs given by the x-ray plate, and showed what he believed to be evidences of improvement in the cases treated by Friedmann's remedy.

F. Kraus remarked that the clinic was acting in the capacity of a neutral host and had no patients to show, as those who had been treated by the remedy were not yet ready for conclusions to be drawn. He referred to one case which had been presented and which he had regarded as affording no prospect of success for the Friedmann remedy. The improvement he regarded as surprising, even when it was admitted that the patient was a very impressionable man. (The patient was the one that Schleich allowed to tell his own history.)

While admitting that these results may be obtained by other methods. Kraus believes that the method gives results better than he has seen obtained by tuberculin. and he regards it as preferable on account of its simplicity. He recommends that it be tested at leisure without prejudice.

36. **Vaccination against Varicella.**—Kling protests against the assumption that chicken-pox is always a harmless disease. When it runs through an institution with many small children, it is liable to develop into a malignant form. It may leave disfiguring scars and sepsis or erysipelas may originate in the pustules, while instances are known of consecutive pneumonia, nephritis, gangrene of the skin and other complications. At the Stockholm Children's Hospital an epidemic of varicella developed last August; forty-four patients were affected and in order to save the rest he inoculated the other

infants with serum from a pustule. A positive response was obtained in fifty-eight of the children and the virus could be cultivated through six generations. Only one of the thirty-one vaccinated infants in two wards developed the disease, and it ran an unusually mild course, while over two-thirds of the non-vaccinated had typical varicella. There are 200 children in all the wards of the institution. The response to the vaccination was slight and exclusively local. A number of the children giving a positive reaction had been vaccinated against small-pox up to a few months before. The typical reaction to both seems to sustain the assumption of the essential difference between variola and varicella.

37. **Action of Hypophysis Extracts on the Kidneys.**—The experimental and clinical research reported by von den Velden shows that extracts of the pituitary body depress kidney functioning. This effect warns of the necessity for caution with this form of organotherapy. It also explains the benefit from it in diabetes insipidus.

38. See abstract 57 in The Journal, 1913, lxi, 1752.

39. **Splenectomy in Pernicious Anemia.**—Mosse adds another case to Eppinger's in which the clinical picture of pernicious anemia was transformed by removal of the spleen. (See The Journal, Oct. 4, 1913, p. 1333; Nov. 15, p. 1816, and Dec. 6, p. 2087.) Of course this treatment is applicable only in cases of pernicious anemia with much hemolysis. The extent of the blood destruction can generally be determined by testing the resisting power of the red corpuscles to salt solution and to the patient's serum and alien serum. Mosse's patient was a woman of 38 and the great benefit following splenectomy has persisted unmodified to date.

44. **Blood-Pressure in Alcoholism, Etc.**—The tests were made in chronic alcoholics with normal heart and kidneys after abstinence had been enforced in the hospital. There was a marked rise in the systolic pressure for a few days, with a gradual fall. The diastolic pressure was constantly high throughout the whole period, so that the increased pulse pressure was caused only by the rise in the diastolic pressure. This peculiarity in the blood-pressure curve is so constant that it could be used in doubtful cases for diagnostic purposes. In functional neuroses the curves were variable and less characteristic.

46. **Effect on Autolysis of Various Pathologic Sera.**—A series of experiments was undertaken to determine the effect of serum in different diseases on autolysis in various organs. The serums from patients with parasyphilitic disease had no appreciable effect on human brain tissue; on the other hand, the serum from patients in certain stages of pneumonia and serum from uremic patients decidedly increased autolysis. Autolysis of rabbit liver was increased by serum from pneumonia, uremia, chronic nephritis, Basedow's disease, the absorption stage of serous joint effusions, diabetic coma and beginning delirium tremens. This effect was not constant, however. It seems that it can be hindered under certain circumstances by anti-autolytic substances in the serum.

This increase in autolysis cannot be attributed either to a decrease in alkalinity of the blood or to drugs, nor to a decrease of the complement or antibodies in the blood. The substances in the serum responsible for it are called auxo-autolytic bodies. They are probably of the nature of ferments. If this proves to be the case, we will thereby have a new and more delicate method of demonstrating proteolytic ferments in the blood-serum. The presence of these auxo-autolytic substances in human serum also confirms the assumption that autolytic processes are going on in the body during life. Differences were noted in the effect of the same serum on the autolytic enzymes of different organs, confirming the specific nature of the autolytic enzymes involved. Serum from pregnant women decreased autolysis of rabbit liver but hastened the autolysis in placental tissue. Other normal and pathologic serums were neutral in regard to placental tissue, while inhibiting autolysis in rabbits' livers. No normal or pathologic serum was found that increased autolysis in tumors.

49. **Retention of Chlorids.**—Scholz and Hinkel find that the question of chlorid retention is much more complicated than has hitherto been supposed. Many other conditions besides nephritis influence retention of chlorids, such as congestion, disturbances of nutrition, anemia and cancer. Therefore high chlorid content of the blood should not be attributed to kidney insufficiency until these other possible factors are excluded. They regard the skin as the main storehouse for the chlorids in the body; after this come in turn the intestines, the liver and the lungs.

52. **Determination of Colloidal Nitrogen in Diagnosis.**—Lehmann found that Kojo-Salkowski's quotient, which is assumed to represent the relation of the colloidal nitrogen to the total nitrogen of the urine, is often increased in carcinoma and tuberculosis. The quotient is markedly influenced by diet. With cancer, for instance, by giving a diet poor in purins, the quotient may be decidedly decreased. On the other hand, by giving normal individuals an excess of purin bodies the quotient may be made as high as with cancer. In using it for diagnostic purposes, therefore, the diet must be carefully controlled. (The test was discussed editorially in The Journal, Sept. 6, 1913, p. 778.)

53. **Care of the Hair and Its Diseases.**—Kromayer reiterates that any means to stimulate the functioning of the hair papilla tends to prevent the dropping out of the hair and promote the production of new hairs. For alopecia areata the best local application seems to be a 1 to 4 per cent. alcoholic solution of mercuric chlorid with which the bald spots are dabbed morning and night. If redness and pain are induced, the application is suspended until this subsides. He regards radiotherapy, however, as far superior to any medicinal applications. The quartz lamp can be applied to induce with the white light an intense inflammation over the bald spot; this is then healed with salves and the application is repeated once. Or the milder blue light can be used daily to keep up a very mild congestion and inflammation. Both forms of radiotherapy with the quartz lamp are very effectual, he says. In not a few cases the hairs began to sprout in a few days after the white light application and by the end of a few weeks there was a normal growth of hair.

Alopecia pityroides is the result of chronic inflammation of the scalp, causing itching and patches of redness and dandruff. The hairs grow fast under this stimulus but gradually the papilla becomes destroyed and permanent baldness results. The baldness thus induced is irreparable but the cure of the causal inflammation and prevention of the inflammation are important and practicable. The scalp needs light and air to be healthy; the constant wearing of hats and caps, and living in close rooms reduce the resisting power of the region while the accumulation of dust, sweat and sebum provides food for micro-organisms. He insists that the scalp should be cleansed much more regularly than is generally done. Men should shampoo their heads with a non-irritating soap two or three times a week and then apply a 5 per cent. petrolatum solution in ether, rubbing in fifteen or twenty drops on a wad of cotton. For women he advises the use of what he calls the hair *Glittel*, a kind of narrow toothbrush only it has a pad of wool in the place of bristles. A weaker solution of the petrolatum can be used or a mild shampoo, afterward replacing the fat lost in the shampooing. The ends of the hairs suffer most from the loss of fat, and consequently he advises women to tie up the long ends of their hair in three or four rubber tissue bags when the scalp is shampooed. He remarks in conclusion that a convenient method has not yet been discovered for removal of superfluous hairs. Even when five needles are inserted at once for electrolysis it takes a great deal of time and there is liable to be recurrence over more or less of the area in the course of a few months in persons with a tendency to much growth of hair.

57. **Cardiospasm and Hypnosis.**—Szöllösy's patient was a woman of 36, otherwise healthy, and in good circumstances. She had suffered for two years from cardiospasm absolutely rebellious to all medical measures. Asthma developed also and the woman became much emaciated from inability to have the food pass regularly into the stomach, but there were no symptoms of hysteria. An operation confirmed the lack of organic trouble. Atropin gave relief for a few hours at first but the patient gradually became accustomed to it and no further effect was apparent. As a last resort hypnosis was tried, and for five weeks during the hypnosis treatment and for a month afterward there was no further disturbance from the neurosis. Then the symptoms returned again the same as before, persisting until permanent relief was obtained by an operation nearly three years after the first signs of trouble.

71 The Wassermann Reaction. (Zur Frage des verfeinerten Wassermann mit bes. Berücksichtigung der sogenannten paradoxen Sera.) F. Graetz.

62. **Outlet of Pleural Effusion with Inlet of Air.**—Schmidt is not convinced of the therapeutic advantages of letting air into the pleura in pleurisy, although he has seen some surprising benefit follow this in occasional instances; but if it is to be done the technic he describes places it within the reach of every one and absolutely free from drawbacks of any kind. It is important to drain away the effusion to the last traces, and this is accomplished in the simplest and most thorough manner by having the patient lie on his side across a narrow space between two beds. The puncture is made at the lowest point with a simple, not too thick, two-way trocar. Removing the guide starts the flow, and as air enters at the same time no aspiration is necessary and there is no need to measure the amount of air; only just enough enters to take the place of the emerging fluid. The conditions in regard to pressure between the outer air and the air in the chest adjust themselves automatically. He has determined with the Roentgen rays that with this technic the fluid drains away to the last drop and no more air enters than takes the place of the fluid. He describes two cases in detail with the Roentgen findings before and after to sustain his assertions.

63. **Syphilitic Disease in Internal Organs.**—Lenzmann's experience teaches that the absence of signs of syphilis by no means excludes the possibility of a syphilitic origin for disturbances observed. The sad "too late" is particularly tragic here as proper treatment in time might have warded them off. He opens the list with two cases of what was apparently cancer of the liver in women nearly 60, free from any suspicion of syphilis, but with cachexia, pallor, emaciation and the liver extending two or three inches below the costal arch, hard and knobby, painful on pressure, but not otherwise, since the first beginning of trouble six months before. Both women had healthy children but each had had two abortions years before. The Wassermann was found positive and under treatment for syphilis a complete clinical cure was realized in a few weeks in both cases. In contrast to these, in a third case, in a known syphilitic woman, an affection of the liver developed which was not influenced by treatment and necropsy showed cancer. The whites numbered 20,150 in this case while in the two others in which the syphilis was responsible for the trouble, the whites numbered about 7,200. Loss of appetite and oppression in the stomach often accompany recent syphilis; there is probably a catarrhal disposition on the part of the gastric mucosa. He has often witnessed later in the course of the disease severe stomach disturbances, vomiting after meals and gastralgia at night, all of which subsided entirely on treatment of the syphilis. This also ocurred in a case suggesting ulcer by the occult bleeding and gastralgia.

One patient with symptoms of obstruction in the intestines for several months finally developed complete ileus and died. Syphilis was not suspected in this case but necropsy revealed gummatous tumors as probably responsible for the entire intestinal trouble. Another patient with signs of syphilis had colics and obstinate diarrhea not influenced by the usual means but subsiding under treatment of the syphilis; the gummatous infiltration of the mucosa had not reached the stage of ulceration. Two other patients had oliguria, high albumin content of the urine, edema, extreme pallor, and they felt very sick, but were restored by treatment for syphilis.

One patient consulted him for obstinate headache and sleeplessness and the urine contained some albumin and casts with a blood-pressure of 150 to 158. These signs of a kidney affection had developed fifteen years after infection with syphilis. Treatment for the syphilis then seemed to arrest the kidney trouble; enough sound kidney tissue was saved so that although there is now, sixteen years later, still 0.5 per thousand albumin in the urine, there are no casts and the patient feels well and strong. In another case with a blood-pressure of 170, normal conditions were restored by specific treatment. Syphilitic disease of the arteries may cause symptoms in time to permit complete retrogression if they are carefully heeded. Sudden loss of consciousness may be the first sign of trouble in the cerebral arteries; he has had three cases of this kind. One was a man of 62 who noticed that he could not rely on his memory and felt depressed; after a few months he suddenly dropped unconscious and lay in this state for three days. The assumption of cerebral apoplexy was disproved by the fact that no paralysis was left from the attack and treatment for the syphilis restored him to apparently complete health as occurred also in two other cases of this kind; the loss of consciousness had lasted only a few hours.

All these experiences emphasize the importance of energetic treatment of the syphilis whenever the Wassermann becomes positive; also that syphilitic patients should be kept under observation for years. He urges the Wassermann test even when there is no history of syphilis but merely headache at night, pain in the heart or other suspicious symptoms. Few syphilitics will take the pains to get cured. They may go to some physician who will reassure them and say "wait for further treatment until you have symptoms." This pleases the patients, and as long as this lack of sense on the part of the public is nourished by the words of certain medical

men the prospects of eradicating syphilis and its tragic consequences are not very bright.

65. **Botulismus.**—Bürger reports twelve cases of meat-poisoning following the eating of ham and sausage from one pig. The physicians who saw the first cases diagnosed diphtheria on account of the redness of the throat, the disturbances in swallowing and a coating in the throat resembling that of diphtheria. This mistake is the more liable because diphtheria toxin may cause injury of the nervous system exactly like that of botulism toxin, but in case of diphtheria injection of a guinea-pig with serum from the patient will cause the adrenals to swell, with a tendency to hemorrhages in the tissues and effusion in the pleura, while in case of meat poisoning there is the characteristic paralysis of the extremities, intestines, bladder, etc. In mild cases of botulismus the muscles of accommodation may be paralyzed but with pronounced poisoning there is also paralysis of the iris. With poisoning from atropin or other plant alkaloids, the nervous symptoms develop much more rapidly than in botulismus, and there may be delirium or unconsciousness; these are not observed with botulismus, while methyl-alcohol poisoning does not show the paralysis characteristic of botulismus.

The treatment of botulismus must be different from that of ordinary meat-poisoning with gastro-intestinal symptoms. On account of the paralysis of stomach and bowels, purgatives and emetics have no effect and merely add to the intoxication as they lie passively in the stomach. The sausage or other substance responsible for the poisoning lies in the stomach indefinitely and consequently repeated rinsing out of the stomach is indispensable even when days have elapsed before the true nature of the disturbances is suspected; lavage may save the patient's life at any stage. Serotherapy is also important, and an antibotulismus serum is on the market, but Kobs has recently reported experiments on guinea-pigs in which ordinary diphtheria antitoxin neutralized the toxic action of botulismus poison. If this experience is confirmed in the clinic a new aid in treatment will be afforded, easier of access than the specific antitoxin. Other measures that may prove useful are venesection, saline infusion, high rectal injections, massage and faradization of the abdomen, inhalation of oxygen and artificial respiration. Necropsy has frequently revealed aspiration pneumonia in the cadavers of botulismus patients, and hence no feeding by the mouth should be allowed.

72. **Prognosis in Heart and Vascular Disease.**—Grassmann presents some statistics which show that the number of persons who die from cardiovascular disease is increasing year by year, while the mortality from cancer and tuberculosis is constantly diminishing. He asks why nothing is being done to reduce this frightful mortality from cardiovascular disease. All our patients with dropsy from cardiac trouble die, and the interval is not long; they die as inevitably, it seems, as those with unoperated cancer. The prevailing pessimism in respect to cardiovascular disease is like that which prevailed in regard to tuberculosis not so many years ago, and he thinks that the outlook will grow brighter in time. There is no doubt that preventive measures can be found that will prove effectual in some forms of cardiovascular disease, especially chronic, inflammatory or degenerative myocarditis or hypertrophy of the heart, toxic influences, thyroid intoxication, syphilitic affections of heart and vessels, injury of the heart from athletics, from overeating, undereating, anemia, and, to a certain extent, arteriosclerosis. Some of these factors are more or less under our control, and we must aim to detect the tendency to cardiovascular disease while it is still in the stage corresponding to the apical process in pulmonary tuberculosis or even before this. The public must be taught the importance of the early diagnosis of cardiovascular disease, just as it is learning the importance of this in tuberculosis and cancer. Grassmann insists that the heart should be systematically examined at intervals just as much as the teeth. He pleads for the establishment of institutes for research on the heart, like the cancer research institutions, and means to give the heart and vessels a chance to recuperate, like the great system at the disposal now of the insured working-man with incipient tuberculosis. Statistics show the pressing need for checking the increasing mortality from cardiovascular disease, and he declares that this is a social and economic public matter calling for a systematic campaign on a large scale.

73. **Serodiagnosis in Scarlet Fever.**—Twenty-seven children with scarlet fever and thirteen controls were tested by the dialysis technic for specific ferments in their serum. With three exceptions, the serum of all the scarlet fever children digested lymph-node tissue when the test was applied between the fifth and thirty-second day of the disease, but none before or after these dates. Positive findings were also obtained in seven of the controls, namely, in a case of hebephrenia, of endometritis, of polyp in the ear, or of acute or chronic polyarthritis, and in two pregnant women. The digestion proceeded the same whether the lymph-node tissue had been derived from a scarlet fever patient or not.

76. **Palpation of the Psoas.**—Further experience with Hausmann's method of deep and sliding palpation has amply confirmed its reliability and instructiveness, he reiterates. He palpates from the front the rear abdominal wall, not using force, but insinuatingly working the finger in—always during expiration alone, working rhythmically as the patient expels his breath and stopping during inspiration. The method is peculiarly useful for palpation of the psoas; the muscle is rendered more prominent by the patient's raising his extended leg. The psoas then forms a firm background on which the intestines above it can be instructively palpated, sliding the finger lengthwise of the psoas, over the intestine. He describes in detail the special findings with different segments of the bowel and calls attention in particular to the information to be obtained from tenderness at any point in the psoas. In normal conditions, pressure does not elicit pain; with a visceral neurosis the psoas may be tender throughout and on both sides. Tenderness at any one point is a sign of organic disease somewhere causing irritation of the nerves or lymphatics crossing the psoas at this point. This is almost constant with chronic appendicitis. He ascribes the pain at McBurney's point to the psoas rather than to the appendix.

Tenderness in the lower psoas may accompany disease in the ovaries or tubes or retroflexion of the uterus, just as McBurney's point may be tender with these. In one of his cases of retroflexion, the pain in the psoas disappeared at once when the uterus was lifted by a pessary. Abnormal conditions in a kidney or ureter are liable to induce the psoas pain; not only the lower part but also and predominantly the upper and middle portions are tender. Discovery of the high psoas pain should direct attention to the upper urinary apparatus. Inquiry should be made as to disturbances in micturition at the time or previously, and the lumbar region should be tapped, not pressed, to elicit local pain, tapping with the ulnar side of the hand along the latissimus. Pain will radiate forward in case of a local affection. The normal will feel no pain and if there is hyperesthesia pain will be felt on both sides; it is possible, however, for kidney or ureter disease to be bilateral. There may be pain on pressure of the sacrolumbar muscle, just below the twelfth rib. The urine must be carefully examined for albumin and sediment. Sometimes with no albuminuria a few red corpuscles may be found in the urine sediment. This triad: psoas pain, pain on concus-

men the prospects of eradicating syphilis and its tragic consequences are not very bright.

65. **Botulismus.**—Bürger reports twelve cases of meat-poisoning following the eating of ham and sausage from one pig. The physicians who saw the first cases diagnosed diphtheria on account of the redness of the throat, the disturbances in swallowing and a coating in the throat resembling that of diphtheria. This mistake is the more liable because diphtheria toxin may cause injury of the nervous system exactly like that of botulism toxin, but in case of diphtheria injection of a guinea-pig with serum from the patient will cause the adrenals to swell, with a tendency to hemorrhages in the tissues and effusion in the pleura, while in case of meat poisoning there is the characteristic paralysis of the extremities, intestines, bladder, etc. In mild cases of botulismus the muscles of accommodation may be paralyzed but with pronounced poisoning there is also paralysis of the iris. With poisoning from atropin or other plant alkaloids, the nervous symptoms develop much more rapidly than in botulismus, and there may be delirium or unconsciousness; these are not observed with botulismus, while methyl-alcohol poisoning does not show the paralysis characteristic of botulismus.

The treatment of botulismus must be different from that of ordinary meat-poisoning with gastro-intestinal symptoms. On account of the paralysis of stomach and bowels, purgatives and emetics have no effect and merely add to the intoxication as they lie passively in the stomach. The sausage or other substance responsible for the poisoning lies in the stomach indefinitely and consequently repeated rinsing out of the stomach is indispensable even when days have elapsed before the true nature of the disturbances is suspected; lavage may save the patient's life at any stage. Serotherapy is also important, and an antibotulismus serum is on the market, but Kobs has recently reported experiments on guinea-pigs in which ordinary diphtheria antitoxin neutralized the toxic action of botulismus poison. If this experience is confirmed in the clinic a new aid in treatment will be afforded, easier of access than the specific antitoxin. Other measures that may prove useful are venesection, saline infusion, high rectal injections, massage and faradization of the abdomen, inhalation of oxygen and artificial respiration. Necropsy has frequently revealed aspiration pneumonia in the cadavers of botulismus patients, and hence no feeding by the mouth should be allowed.

72. **Prognosis in Heart and Vascular Disease.**—Grassmann presents some statistics which show that the number of persons who die from cardiovascular disease is increasing year by year, while the mortality from cancer and tuberculosis is constantly diminishing. He asks why nothing is being done to reduce this frightful mortality from cardiovascular disease. All our patients with dropsy from cardiac trouble die, and the interval is not long; they die as inevitably, it seems, as those with unoperated cancer. The prevailing pessimism in respect to cardiovascular disease is like that which prevailed in regard to tuberculosis not so many years ago, and he thinks that the outlook will grow brighter in time. There is no doubt that preventive measures can be found that will prove effectual in some form of cardiovascular disease, especially chronic, inflammatory or degenerative myocarditis or hypertrophy of the heart, toxic influences, thyroid intoxication, syphilitic affections of heart and vessels, injury of the heart from athletics, from overeating, undereating, anemia, and, to a certain extent, arteriosclerosis. Some of these factors are more or less under our control, and we must aim to detect the tendency to cardiovascular disease while it is still in the stage corresponding to the apical process in pulmonary tuberculosis or even before this. The public must be taught the importance of the early diagnosis of cardiovascular disease, just as it is learning the importance of this in tuberculosis and cancer. Grassmann insists that the heart should be systematically examined at intervals just as much as the teeth. He pleads for the establishment of institutes for research on the heart, like the cancer research institutions, and means to give the heart and vessels a chance to recuperate, like the great system at the disposal now of the insured working-man with incipient tuberculosis. Statistics show the pressing need for checking the increasing mortality from cardiovascular disease, and he declares that this is a social and economic public matter calling for a systematic campaign on a large scale.

73. **Serodiagnosis in Scarlet Fever.**—Twenty-seven children with scarlet fever and thirteen controls were tested by the dialysis technic for specific ferments in their serum. With three exceptions, the serum of all the scarlet fever children digested lymph-node tissue when the test was applied between the fifth and thirty-second day of the disease, but none before or after these dates. Positive findings were also obtained in seven of the controls, namely, in a case of hebephrenia, of endometritis, of polyp in the ear, or of acute or chronic polyarthritis, and in two pregnant women. The digestion proceeded the same whether the lymph-node tissue had been derived from a scarlet fever patient or not.

76. **Palpation of the Psoas.**—Further experience with Hausmann's method of deep and sliding palpation has amply confirmed its reliability and instructiveness, he reiterates. He palpates from the front the rear abdominal wall, not using force, but insinuatingly working the finger in—always during expiration alone, working rhythmically as the patient expels his breath and stopping during inspiration. The method is peculiarly useful for palpation of the psoas; the muscle is rendered more prominent by the patient's raising his extended leg. The psoas then forms a firm background on which the intestines above it can be instructively palpated, sliding the finger lengthwise of the psoas, over the intestine. He describes in detail the special findings with different segments of the bowel and calls attention in particular to the information to be obtained from tenderness at any point in the psoas. In normal conditions, pressure does not elicit pain; with a visceral neurosis the psoas may be tender throughout and on both sides. Tenderness at any one point is a sign of organic disease somewhere causing irritation of the nerves or lymphatics crossing the psoas at this point. This is almost constant with chronic appendicitis. He ascribes the pain at McBurney's point to the psoas rather than to the appendix.

Tenderness in the lower psoas may accompany disease in the ovaries or tubes or retroflexion of the uterus, just as McBurney's point may be tender with these. In one of his cases of retroflexion, the pain in the psoas disappeared at once when the uterus was lifted by a pessary. Abnormal conditions in a kidney or ureter are liable to induce the psoas pain; not only the lower part but also and predominantly the upper and middle portions are tender. Discovery of the high psoas pain should direct attention to the upper urinary apparatus. Inquiry should be made as to disturbances in micturition at the time or previously, and the lumbar region should be tapped, not pressed, to elicit local pain, tapping with the ulnar side of the hand along the latissimus. Pain will radiate forward in case of a local affection. The normal will feel no pain and if there is hyperesthesia pain will be felt on both sides; it is possible, however, for kidney or ureter disease to be bilateral. # CONTROL OF CANCER*

JOSEPH COLT BLOODGOOD, M.D.
BALTIMORE

We now have evidence to show that the number of cures of cancer can be increased. No one will question that cancer of the lip, tongue, skin, stomach and colon has been cured by radical excision. There was a time in the history of surgery when no such cures had been accomplished. In 1890, Agnew, professor of surgery at the University of Pennsylvania, made the public statement in his surgical clinic that he had never cured a patient of cancer of the breast. Within a few weeks I have seen a patient operated on for cancer of the breast by Dr. Halsted in 1890, who is still living and apparently as free from signs of cancer as a person who had never suffered from that disease.

Agnew, who honestly stated that he had never cured cancer, only removed the breast and never operated, except when the signs of cancer were fully developed. Halsted, in 1890, removed not only the breast, but a wide area of skin, both pectoral muscles and the axillary contents *en bloc*. Halsted also operated the moment he was given the opportunity.

When the first statistical study from the Johns Hopkins Hospital was published, showing 47 per cent. of patients apparently free from cancer three years after operation, most surgeons in this country were skeptical as to the truth of these statistics. Every few years a reinvestigation of the results confirms the original statement.

The number of cures of cancer can be increased by earlier intervention and better surgery. The American Society for the Control of Cancer hopes to bring before the public and the profession the actual percentage of cures of cancer accomplished in the various clinics in this country. In these clinics complete records have been kept; in each case the diagnosis has been checked by competent pathologic examination, and in many instances the original tissues and microscopic sections have been preserved for restudy—therefore, for a confirmation of the original diagnosis.

Many physicans to-day are skeptical as to the permanency of the cure of cancer. They question the pathologic diagnosis in the cases in which the patients have lived ten years or more. In the clinics just referred to, in which the records and the tissues have been preserved, the histologic picture of the tumor in the case of a cure does not differ from the histologic picture of the case or cases in which the patients later died of cancer. When, therefore, we have for every case in which the patient was cured a histologically identical case in which the patient was not cured, it is fair to assume that the patient cured also suffered from cancer.

The majority of people believe that cancer is a "blood disease." By this they express a vague notion of a general disease present in many parts of the body, and for this reason they naturally conclude that its removal from one place will have no effect on the disease in other parts.

The majority of surgeons who operate for cancer do not always tell their patients the nature of the disease, but, whether they do or not, the longer the patient lives in comfort the more skeptical does he or she become as to the grave nature of the original disease. Especially, is this true in cases in which the operation was necessarily mutilating, as in skin-grafting in operations for cancer of the breast, or in resection of the jaw in cancer of the tongue and gum, or in some cases of amputation for carcinoma or sarcoma of the extremities. Again and again, in the course of my investigation of the ultimate results in malignant disease, I have encountered in correspondence and conversation the questions: Was it necessary to do so much? Was the disease really cancer?

In the control of cancer, therefore, we shall have to combat this skepticism both in the ranks of the profession and among the people. We have the evidence that cancer can be cured and we must bring it before the profession and the public in such a way that they will believe it.

The percentage of cures in the fully developed cancer is relatively small. The exact figures differ with the localizations. By fully developed cancer I mean one in which there can be no question as to the histologic evidence of malignancy. In this type, too, cures have been accomplished and, while the percentage of these cures is relatively smaller, the possibility of increasing it is by no means out of the question. There is great difference pathologically and clinically between fully developed cancers. A tumor is clinically malignant, or cancerous, when the examining clinician is able to make the diagnosis of the condition without the aid of the gross appearance of the tumor cut with the knife or a microscope section.

When cancer is clinically malignant the probability of a cure is relatively smaller than when it is only histologically malignant, but has not as yet assumed the clinical picture of cancer. This is well illustrated in cancer of the breast. In the Johns Hopkins Hospital surgical clinic, among those cases in which previous to operation a clinical diagnosis of cancer could not be made, the proportion of cures five years after the radical operation is 80 per cent. In these cases the diagnosis was made at the exploratory incision either from the gross appearance of the tumor after it had been cut into or from the frozen section.

---

* An address delivered before the Lehigh Valley Medical Society, June 17, 1913.

In those cases in which the diagnosis of cancer could be made clinically from the retracted nipple or adherent skin, the proportion of cures after five years is about 25 per cent. It is an important thing to state that there is absolutely no difference in the pathology of the clinically malignant cancer of the breast and the cancer which cannot be distinguished clinically from a benign tumor.

We may divide cancer of the breast into different forms of adenocarcinoma, scirrhus and medullary carcinoma and cancer cysts, and in each group we shall find some cases subjected to the complete operation in that early stage in which the diagnosis could be made only at the exploratory incision and some in that later period when malignancy was written on the condition by changes in the skin and nipple. The same differences in the results are seen in the different types of cancer. One cannot tell with the microscope, unless one has a section near the skin or nipple in which the infiltration of the tumor is shown, whether this cancer was clinically malignant or not. It is the same type of cancer, therefore; yet, in one case the patient has eighty chances to only twenty-five in the other. The two are subjected to the same operation by the same operator, yet the probabilities of a cure are influenced chiefly by this fact: When the cancer is clinically malignant the chances of a cure are worst; when it is clinically benign, best. This fact is true of cancer in every localization, and the truth of this statement must be impressed on the entire profession and the people. The old method of waiting for the signs of cancer simply means decreasing the probability of a cure. The same is true of cancer of the lip, the tongue, the skin of the face, body and extremities, the uterus, stomach, colon, etc.. The danger of the length of delay varies with cancers in these different localizations.

We have evidence which suggests that, when the disease is treated before it has become clinically malignant, the number of cures of cancer can be increased far beyond the number of cures already accomplished in cancer.

In every localization in which we encounter cancer, we also meet lesions which, histologically, are not cancer. When these lesions are radically removed we never observe recurrence or death from cancer which could be attributed to the tumor removed. It would hardly be right to call these cases cures of cancer, but, as a matter of fact, the time may come when so many patients present themselves for treatment with tumors or lesions in this stage that we shall at once begin to observe in all clinics a decrease in the numbers of cancer cases. It is possible, therefore, in some localizations of cancer to hope for complete eradication of any uncured cancer. These lesions, which histologically are not cancer and which are curable up to 100 per cent. by radical removal, may be called precancerous.

In external cancer, when the patient is carefully questioned, we can usually obtain a history of the beginning of the disease which later comes under observation as cancer. Among 820 pathologically fully developed cancers of the skin and visible mucous membranes, I was unable to find, in a well-taken history, the absence of a previous defect which might be looked on as a benign precancerous lesion. At present, among 997 epithelial tumors of the skin and visible mucous membranes, 173 have been histologically benign, and there was not a single failure to cure in this latter group. The actual proportion of these lesions has increased from 17 to 39 per cent. in two years. Does this mean that we have actually prevented cancer, or does it simply mean that we have removed warts and benign ulcers which would have disappeared if we had left them alone?

We have not, to-day, the figures to prove that the routine and proper removal of these benign, so-called precancerous lesions will reduce the number of deaths from cancer, but the recent evidence is suggestive. In my investigation of cancers of the skin and mucous membranes the worst results are seen in cancer of the tongue. At present we have records of and tissues from thirteen benign and seventy-one malignant lesions of the tongue. These thirteen benign lesions have all been obtained in the past five years, most of them in the past two years. Until three years ago we had never observed a cancer of the tongue at so early a stage that there was any doubt as to the correct diagnosis, but in the past two years we have had six early cases. Up to the present time we have had about 20 per cent. of cures in cancer of the tongue. The experience of the past two years indicates that the proportion of cures will be increased to 40 per cent. I feel confident that no one should fear cancer of the lip, tongue or skin, if he is only educated to the potential dangers of these precancerous lesions, provided that a person so educated obtains in this stage the advice and treatment of a properly trained surgeon. I also feel confident from my investigation that the number of deaths from cancer of the skin and visible mucous membranes, such as lip, tongue and cheek, will be greatly decreased; more operations will be done for the precancerous lesions with 100 per cent. of cures; more operations will be performed for the histologically fully developed cancer, but in that early stage in which it cannot be diagnosed clinically and in which the probability of a cure, while not 100 per cent., is still best. Fewer operations will be performed for cancer clinically malignant with its relatively low possibility of a cure, and in fewer cases will patients present themselves with inoperable cancer.

In cancer of the stomach, colon, appendix, gall-bladder, pancreas, etc., it is more difficult to demonstrate the precancerous lesion. Is it fair to look on every cured resected ulcer of the stomach as a cured cancer? There is no doubt that the histologically fully developed cancer of the stomach has been cured by pylorectomy. The results have been best when the clinical symptoms have been least and of the shortest duration. When a clinical diagnosis of cancer of the stomach or colon can be made, the probability of a cure is least. Fortunate is the patient with cancer of the stomach or colon whose tumor produces obstruction early, because the symptoms then urge operation. Unfortunate, and, in the majority of cases, doomed, is that patient the symptoms of whose neoplasm are slight.

If it has been difficult to educate people and the profession as to the potential danger of a lump in the breast, small and painless defects of the skin and mucous membranes and irregular bleeding from the uterus, it will be much more difficult to educate them to the significance of abdominal pain, indigestion and changes in the stools. The lump in the breast and the precancerous lesion are usually visible and always palpable, but these abdominal symptoms are vague. Patients suffering with them are impatient even of diagnostic measures. They desire immediate relief by diet or drugs. The control of cancer is therefore a problem of education. Those clinics which have the records, the pathologic proofs, must work up their statistics so that we may increase our evidence in proof of the statement that cancer has been cured. Every cured patient is additional evidence.

These clinics can also furnish evidence of the increased probability of a cure in the early stages of cancer and the absolute certainty of a cure in the precancerous stage.

When patients seek advice in these earlier stages, the best results also depend on good surgery. We must establish in this country, on the available evidence, greater uniformity in the treatment of cancer in the different localizations.

No surgeon to-day should operate on a lump in the breast unless he is prepared for the complete operation for cancer if the tumor should prove malignant after exploration. The object of exploring every lump of the breast immediately is not so much to remove a possible benign tumor as to remove cancer in its most curable stage. No surgeon should remove a lump in the breast for microscopic study, delay a few days or weeks and then perform the complete operation for cancer if the tissues studied microscopically should prove to be malignant, because the patient whose chances to be cured were at least 80 per cent. will by such a procedure be almost doomed to death from cancer. The diagnosis must be made at the exploration of the tumor, and, in cases of doubt, the complete operation for cancer must be done.

No surgeon to-day should remove the breast alone for cancer. A few cures have been accomplished, but not enough to justify the procedure, even in exceptional cases. The mutilation of the most radical operation for cancer of the breast with skin-grafting, if properly performed, is nothing as compared with the possibility of a recurrence when a restricted operation has been performed.

Patients with malignant disease—carcinoma and sarcoma—present themselves for surgical aid in the following groups:

A. Hopeless, inoperable. There is no hope even for the palliation of the symptoms by any operation.

B. Inoperable, hopeless. Attempts to relieve pain and prolong life by some operative procedure.

C. Clinically malignant. Apparently operable, but at the operation the disease is found to have extended beyond possible removal with the knife or cautery.

These three groups—A, B and C—really represent inoperable cancer, and up to the present time have been incurable. I shall not discuss here the rare cases of spontaneous cures, the now and then apparently accomplished cures with radium and the Roentgen rays and the apparent cures of inoperable sarcoma with the toxins of prodigiosus and streptococcus.

For these miserable patients everything should be done; every method of treatment should be attempted. No surgeon or physician should allow skepticism to stay his hand or dampen his enthusiasm in attempting to help them. Admitting that there have been some few cures, admitting that there may be more, the percentage will be so small that no one with the knowledge of the true facts would delay to take his gambler's chances with treatment in this late and practically hopeless stage.

We do not often hear these hopeless groups mentioned except in statistical articles and larger monographs. Few physicians and surgeons and fewer of the people realize that in cancer in every possible localization the number of patients in these hopeless groups varies from 25 to 50 per cent.

In external cancer this hopeless condition is due to delay on the part of the patient from ignorance or fear. It is often due to procrastination (probably based on ignorance) of physicians consulted in the early stage. The hopelessness of delay in this group has often been increased by improper intervention, often early and in the most favorable time. The intervention is of various types—incomplete excision by those not trained in surgery; the cutting out of pieces for diagnosis; application of caustics of every type by those of our own guild (I trust, only by those ignorant of the danger) or by quacks, and with Roentgen rays and radium by enthusiasts.

It is to be remembered and emphasized that the treatment received by these patients is, as a rule, instituted in an early period, when experience shows that the best assurance of a cure is the radical cutting out of the disease with a knife in conjunction with, in some cases, the electric cautery. It should not be difficult almost to eliminate these hopeless groups of external cancer.

The clinical symptoms of a cancer of the uterus are so distinct that it should not be difficult to educate the patients and the profession, but unfortunately, even at present, the percentage of patients with cancer of the uterus seeking expert surgical advice in the inoperable group is still large. Thus far our educational efforts have not produced satisfactory results. We trust that later figures will be more encouraging.

In cancer of the stomach, gall-bladder, pancreas, colon, etc., in what we might call internal cancer, the educational problem is a much more difficult one. The beginnings of these malignant diseases are often insidious and slow, and the symptoms are not sufficiently distressing for the patient to be willing to undergo an operation for their relief.

We have trained ourselves to remove the appendix when the patient is suffering no discomfort at all and often when the attacks have been insignificant. We do not always remove the appendix, therefore, to relieve the patient of suffering, but often only to protect him from death from peritonitis. The inoperable groups of internal cancer will remain large until we have educated ourselves and others to understand that the object of exploratory laparotomy in a large number of cases is not so much the relief of symptoms as the protection of the patient from death from cancer.

William Mayo has recently shown that the largest number of patients with cancer of the stomach tell their physicians of symptoms from which they have suffered for from one to three years and longer, and which may be described as ulcer symptoms. Now, as a matter of fact, most people prefer ulcer symptoms to surgery of the stomach. Unfortunately, there is a difference of opinion as to ulcer symptoms and what they mean.

Surgeons whose aid is sought as a last resort feel from the evidence open to them that ulcer symptoms should be looked on as a distinct warning. The object of surgical intervention, then, is just as much for the protection from death from cancer as for the relief of the symptoms. In the early stage of ulcer symptoms the chances of curing cancer are the best.

We have the same available evidence for all forms of internal cancer, but at present there is no uniformity of views among the profession in regard to earlier intervention. The American Society for the Control of Cancer can be most helpful if it is able to collect the evidence which will absolutely prove to, and completely persuade, the large majority of the profession that laparotomy for minimum symptoms, or ulcer symptoms, has for its chief object the cure of cancer. This cure is accomplished either by removing the benign lesion which later might become cancer, or the early cancer already histologically present.

The patients with operable malignant disease may be divided into the following groups:

D. Clinically malignant. In this group, wherever the cancer may be situated, clinical symptoms have developed which, experience shows, with few exceptions indicate malignancy as definitely as the microscope.

E. Clinically benign. In this group the lesions, whether external or internal, exhibit none of the symptoms associated with malignancy. The nature of the disease is revealed either at the operation or later, after microscopic study.

In external cancer the diagnosis of malignancy may be made at the exploratory incision with or without the aid of a frozen section. In internal cancer we often make the diagnosis by palpation of the lesion after laparotomy.

The point that I wish to emphasize is this: So far as the operation goes, the surgeon can distinguish little difference between many of the clinically malignant and clinically benign cases. The axillary dissection in the breast lesion is just as favorable, the resection of the stomach just as simple. If these groups are carefully and properly selected, however, the difference becomes manifest after five years in the results—in the breast 80 per cent. of cures instead of 25 per cent. It seems to me that this evidence should influence every one to prefer the chances of an operation in that clinical stage in which the symptoms are either doubtful or entirely free from any evidence of malignancy rather than take chances in delay. Another factor is to be borne in mind: An operation at this stage, properly performed, should do no harm, and, even though it reveals no malignancy in its earlier stages, it may remove a focus in which the probability of development of cancer is great. This leads to the next operable group:

F. The precancerous lesion. Undoubtedly the hope for the almost complete eradication of cancer rests on the recognition and complete eradication of the precancerous lesion, whatever this may be.

In conclusion, the evidence which allows these deductions is based on the entire surgical experience of many surgical clinics, the results of which are carefully checked by pathologic examinations, and the ultimate results of which five and more years after operation are known.

The control of cancer, therefore, appears to be a matter of education and the chief object of the American Society for the Control of Cancer is to hurry on this education, so that more lives may be saved to-day.

I cannot refrain from adding the following argument in favor of surgical treatment in the precancerous or in the very early malignant stage, when the lesion is still relatively benign. Cancer in this stage is an "economical disease," at least, relatively. The expense of treatment is little, either to the hospital or to the patient, and the period of disability is short.

For most cases of external precancerous lesions, or the early stage of cancer still clinically benign, the lesion can be cut out under local anesthesia. The ordinary charge of the hospital for material at such an operation is from five to ten dollars. Most of these patients need not remain in the hospital, and often they will lose but a day or two from business. The period of disability after the complete breast operation varies from three to four weeks. The period of disability after a pylorectomy, a resection of the colon or a hysterectomy should not be more than three or four weeks. Operation in this early stage has practically no mortality, the postoperative discomforts and complications are least and the period of disability short. Delay simply means more expense to the hospital and to the patient, more danger, greater discomforts and decreasing probability of a cure.

904 North Charles Street.

# THE MUNICIPAL REGULATION OF MILK-SUPPLY *

EDWIN O. JORDAN, Ph.D.
Professor of Bacteriology, University of Chicago
CHICAGO

This paper is not concerned with the advisability of regulating the production, transportation, handling, and distribution of milk. I take it for granted that there is general agreement that the milk-supply should be subject to official supervision and regulation, just as any other matter affecting the health interests of a considerable number of citizens.

On the other hand, the character of the milk ordinances and rules in force in this country at present, the relation of state to municipal control, and especially the particular methods that experience seems to indicate as most effective are questions that it may be profitable to consider.

A few facts may first be presented bearing on conditions in the United States to-day. The data were obtained from answers to a set of questions sent out from the office of the American Medical Association to the health officers of all municipalities with over 25,000 population. The questions were not intended to cover all possible or desirable phases of milk regulation, but to elicit information on certain points thought to be significant of the scope and nature of present municipal control.

There were 229 cities in the United States in 1910 with a population of over 25,000. One hundred seventy-three of these replied to the questions. For convenience the cities were divided into five groups.

Group 1.—Population over 800,000; eight cities; no reply from Pittsburgh, Pa.

Group 2.—Population 100,000 to 500,000; forty-two cities; no reply from Jersey City, N. J., Oakland, Cal., or Worcester, Mass.

Group 3.—Population 75,000 to 100,000; twenty-two cities; no reply from Houston, Tex., or Reading, Pa.

Group 4.—Population 50,000 to 75,000; thirty-six cities; no reply from Akron, O., Charleston, S. C., Peoria, Ill., South Bend, Ind., or Waterbury, Conn.

Group 5.—Population 25,000 to 50,000; 121 cities; no reply from Amsterdam, N. Y., Auburn, N. Y., Bay City, Mich., Bloomington, Ill., Chester, Pa., Dubuque, Ia., East Orange, N. J., Green Bay, Wis., Kingstown, N. Y., Lewiston, Me., Lincoln, Neb., Malden, Mass., Manchester, N. H., Newark, O., New Rochelle, N. Y., Quincy, Ill., Quincy, Mass., Chicopee, Mass., Shenandoah, Pa., Shreveport, La., South Omaha, Neb., Springfield, O., Waco, Tex., Warwick, R. I., Woonsocket, R. I.[1]

Some of the answers to the questions are presented in tabular form (Tables 1 and 2).

It is seen that the requirement of a permit or license is practically universal in all cities of over 50,000 inhabitants. Some cities in the 25,000 to 50,000 group, however, require no permit and a considerable number have no ordinance regulating the sale of milk in any way.

A license requirement seems to be the first step toward proper control. It may be recalled that when the New York City Board of Health adopted an ordinance requiring all persons dealing in milk to secure a permit, the right was contested and carried to the Supreme Court

---

* Read at the Conference of the American Medical Association on Medical Education and Legislation, Chicago, Feb. 25, 1913.

[1] There is reason to believe that the majority of cities in this group from which no reply was received have practically no regulation of the milk-supply.

of the United States. That tribunal sustained the ordinance as a reasonable exercise of police power.

Dairy-farm inspection of some sort is carried on by the great majority of cities. This unquestionably varies in efficiency. The frequency of inspection ranges from "once in a year or two" and "when necessary" to regular monthly examinations. In general it seems to be true that dairy-farm inspection is more regularly and more effectively carried out by cities with a population of over 100,000 than by smaller municipalities. This is perhaps in part due to the larger sums of money available for health purposes in the larger cities, but it must be remembered that the farms supplying towns of 25,000 to 50,000 are relatively few in number and near at hand, so that the absolute expense of efficient inspection would not be great.

The score-card of the United States Department of Agriculture is commonly but by no means universally used. The dairy score-card, while undoubtedly of service, does not in the opinion of many health officers give a sufficiently satisfactory basis for judging the character of the milk reaching the consumer. General methods of grading the supply on the basis of all available information, like those in use in New York City and Washington, D. C.,[2] seem to be growing in favor in the larger cities.

TABLE 1.—REGULATION OF MILK-SUPPLY IN CITIES*

* Numbers in brackets indicate the number of cities not answering question.

A number of municipalities require that the tuberculin test be applied to herds furnishing milk, but the requirement is far from universal (33 per cent.). Bacterial standards for raw milk, ranging from 100,000 to 5,000,000 (this is the only one over 1,000,000!) have been established by the large majority of cities with over 100,000 population (forty-six cities in Groups 1 and 2). Sixteen cities out of forty-six reporting fix a limit of 500,000. The cities with 25,000 to 50,000 population are much more generally without bacterial standard, largely, doubtless, because of the lack of suitable laboratory facilities for enforcing such a requirement.

The process of pasteurization is much more extensively employed in some cities than in others. In some of the larger cities, as much as 70 to 80 per cent. of the whole supply is pasteurized. About 30 per cent. of the cities with over 100,000 population have half or more of their supply pasteurized. A very striking feature of the reports is the general absence of any regulation dealing with the pasteurizing process, even in municipalities where a large proportion of the supply consists of heated milk. A number of health officers state that this condition will be remedied soon by the passage of ordinances dealing with the legal definition and control of pasteurization. A smaller proportion of the cities in the 25,000 to 50,000 group report pasteurization of any considerable part of the supply, but in them also, the pasteurizing process is evidently gaining ground. It is unfortunately true that supervisory control of pasteurizing plants is no more general in the small than in the large cities.

A comparison of the milk supply conditions in 1912 (Table 2) with those prevailing ten years previously is facilitated by a study made in 1902 by Alvord and Pearson[3] of the U. S. Department of Agriculture. Briefly stated, some of the principal changes in ten years appear to be:

1. An increase in the retail price of milk has occurred in all parts of the United States and averages 2 to 3 cents a quart (in some localities certainly the greater part of the increase has gone directly to the producer).

2. An extensive development in methods of supervision and an increase in the amount expended for supervision have taken place. The city of Denver spent $1,200 for all supervision in 1902, $5,000 for farm inspection in 1912. Ten years ago the city of St. Louis spent $1,850 for the supervision of its milk-supply, in 1912, $5,650 was spent for farm inspection alone. Chicago expended about $10,000 for the whole supervision of its milk-supply in 1902 and about $25,000 on farm inspection alone in 1912. New York made 41,292 farm inspections in 1912 at a cost of $76,080. The same change has occurred in some cities of 25,000 to 50,000 population. Haverhill, Mass. (population 44,000), which expended $150 for supervision of the milk-supply in 1902 had increased the amount to $1,600-$1,700 in 1912. Little Rock, Ark., which reported no milk ordinance and no supervision over its milk-supply in 1902 was spending $3,750 for farm inspection in 1912. Together with this increase in

[3] Alvord and Pearson: The Milk-Supply of Two Hundred Cities and Towns. Bureau of Animal Industry, Bull. No. 76.

the amount expended for supervision has gone a change in the character of the supervision, which can on the whole be regarded as advantageous from the public health standpoint. It can no longer be said, as it was said in 1902, that "most of the inspection work consists in testing samples of milk to ascertain if they contain as much fat and other solids as required by the standard." There is no doubt that at present much more attention is paid to matters of real sanitary significance, such as the health of the cows, the conditions under which milk is collected and transported, and the health of persons handling the milk, than was the case ten years ago. It is encouraging to note also that the practice of adulteration and the addition of preservatives do not seem at present to be as widespread as formerly.

While there can be no doubt that the development in dairy inspection which has occurred in the last ten years has been on the whole in the right direction, it seems particularly important not to invite criticism from the sensitive agricultural interests by placing this branch of milk control in unskilled hands. When it is possible to make a statement like the following, the need of carefully appraising the competency of would-be milk inspectors is apparent.

"In the case . . . mentioned all but nine out of 343 dairies were condemned by the 'inspectors.' The inspectors were aged 26 and 21, respectively. The elder had never lived or worked on a farm, or in a dairy; his education to qualify him to make about half of the above noted inspections was gained in attending a dairy school from ten to fifteen days. Armed with the knowledge thus acquired, he in one day 'instructed' his associate, who had never lived on a farm or worked in or seen a dairy. With this one day's instruction our 21-year-old inspector condemned the other half of the above-mentioned dairies. This is taken from the sworn testimony of the 'inspectors' acting for a city having a population of over 200,000."[4]

Such extreme instances as the cases above cited are probably not common, but there is reason to believe that the cause of much opposition to reasonable milk standards and regulations may be traced to the vexation produced in farmers and dairymen by the acts and utterances of ignorant or overbearing inspectors.

It is questioned by some whether the large sums of money expended in dairy-farm inspection and score-card rating have really given an adequate return in the prevention of communicable diseases. It is pointed out that the real danger to the public health lies not so much in the entrance of cow manure into milk, objectionable as this is, as in the actual infection of the milk with disease germs. However this may be, there is no doubt that farm inspection with all its shortcomings has done much in the last decade to raise the standards of rural sanitation as well as to improve the general character of city milk supplies. Whether or not as a public health measure it deserves all the emphasis we are now placing on it is a matter for future experience to determine.

3. A particularly noteworthy change that has occurred in the past ten years has been the growth of the process of pasteurization. In New York City it could be said ten years ago that "perhaps 5 per cent. of the total milk-supply is pasteurized," while it was true in 1912 that 40 per cent. of the supply was pasteurized. In Boston the report in 1902 was that "very little pasteurized milk is on the market and it is not increasing in favor," but 75 per cent. of the market milk was pasteurized in 1912. The same change may be remarked in smaller cities. Instances picked at random are: Springfield, Mass., with "no milk pasteurized" in 1902, but with 20 per cent. pasteurized in 1912; Lansing, Mich., with "a very small amount" in 1902 and one-third in 1912; Aurora, Ill., with 10 per cent. in 1902 and 85 per cent. in 1912. Whether or not one believes this to be a change for the better, the actual conditions should be recognized and ampler provision made for supervising the process of pasteurization. At present many municipalities possess no regulations governing this important matter.

Without entering at this time into a further analysis of the answers to the questionnaire it is worth noting that of 172 health officers from whom replies have been received 80, or nearly one-half, regard their present local regulations for the control of milk-supply as unsatisfactory. The improvements suggested include such matters as better facilities for maintaining a bacterial standard, more ample provisions for the enforcement of existing regulations, strict application of the tuberculin test, while in a good many instances—towns of from 25,000 to 50,000—the desideratum is a proper milk ordinance. Some health officers suggest compulsory pasteurization either of all milk or of all milk not obtained from tuberculin-tested herds. The admirable New York City rules and regulations relating to the sale of milk are specifically mentioned in some cases as the goal to be reached.

On the technical-legal side two points may be touched on: (1) the need for a uniform or uniformly efficient milk ordinance which shall cover the essential requirements clearly and concisely and shall be open neither to the charge of legal vagueness nor technical inadequacy,' and (2) the proper adjustment of state and local control. As an illustration of the present muddled situation respecting the first of these points I have collated some thirty-nine excerpts from milk ordinances dealing with the single question of milk delivery at houses where there is any contagious disease. The number of words in which this topic is dealt with in the various regulations ranges from 27 to 197. Many of the regulations examined prohibit the leaving of bottles or other milk containers, but allow milk to be poured by the milkmen into receptacles furnished by the families. When delivery of receptacles is allowed, the board of health is often, but by no means always, made responsible for overseeing their disinfection, before again passing them into circulation. One municipality declares that bottles must be sterilized by boiling "in water kept at the boiling-point for fifteen minutes, said sterilization to be done by the party using the milk." The milk dealer is made responsible for seeing that these directions are carried out and is to be penalized for receiving "such bottles not so treated" by having his license suspended or revoked! One of these sections recites that "no person, persons, firm, corporation or association shall refill any receptacle without being first washed," etc. Another guards against legal misunderstanding by the following language:

> It shall be unlawful for any person to serve any milk, cream, buttermilk, skimmed milk, pasteurized milk, condensed or evaporated milk, or condensed or evaporated skimmed milk, in bottles to any dwelling in which any person is ill with any contagious, infectious, or communicable disease, or to any dwelling on which there is a placard or notice stating or indicating that any person therein is ill with any contagious, infectious, or communicable disease until after such placard shall have been removed by the proper officer.
>
> It shall be unlawful for any person to remove from any such dwelling any bottle or receptacle which shall have been

---

[4] Carlin: Creamery and Milk Plant Monthly, 1912, i, 10.

> or is to be used for the purpose of receiving, storing, or delivering milk, cream, buttermilk, skimmed milk, pasteurized milk, condensed or evaporated milk, or condensed or evaporated skimmed milk, or into which any milk, cream, buttermilk, skimmed milk, condensed or evaporated milk, or condensed or evaporated skimmed milk shall have been or is to be placed, or which is commonly used for the reception, storage, or delivery of milk, cream, buttermilk, skimmed milk, pasteurized milk, condensed or evaporated milk, or condensed or evaporated skimmed milk.

The confusion and divergence shown in both wording and intent are sufficient to demonstrate the desirability of drafting a model milk ordinance, which shall allow modifications for local conditions, and shall fit especially the needs of communities with from 25.000 to 75,000 inhabitants. Larger cities are at present fairly well off in the matter of milk regulation, but many of the smaller cities are without any ordinance at all and the health officers, as shown by their answers to the questionnaire, would welcome the opportunity to press for an ordinance backed by the prestige of some influential body of workers. Some of the discrepancy in practice and the confusion of legal phraseology which exist now in the milk rules of a few of the large cities might be cleared up also by an open discussion of the essential points to be included in a model ordinance.

The relation of local to state and federal control of health matters opens a wide question which can only be touched on here. Possible conflict between municipality and state in health matters is illustrated in the extraordinary act passed by the Illinois legislature on the tuberculin test.

> It shall be unlawful for any city, village, incorporated town, county, or other incorporated authority by ordinance or otherwise to require the tuberculin test to be applied to dairy animals as a means of regulating and purifying milk, skimmed milk, cream, and other dairy products. Every such ordinance or regulation passed by any corporate authority other than the state of Illinois is declared void. (Filed, June 12, 1911, became a law without the governor's signature.)

This is an interesting reversal of the theory that the local authorities are likely to be derelict in health matters and that the state must step in and set things right. There is at present no legitimate appeal from such action on the part of the state. In practically all states of the Union the source of authority both for the creation of administrative bodies in health matters, and for the exercise of their power, resides in the state legislature.

Not only may a good regulation be superseded or annulled by a state enactment, but duplication and confusion may be brought about by the existence of conflicting state and municipal regulations. This is particularly so in a matter like milk-supply, where the protection of public health may require interference with an economically important and politically influential interest. City dwellers may be at the mercy of the embattled farmers to a practically limitless extent. Fortunately a spirit of fair play often prevails and the predominantly agricultural counties rarely attempt to club the cities into submission. This is all the more reason for recognizing the present unsatisfactory situation.[5]

In many states there are two sets of inspectors, state and metropolitan, visiting the same farms and attempting to regulate the same industry. Even when regulations do not actually clash state and city are apt to have somewhat different standards, and state and city inspectors will approach the dairy-farms from quite different points of view, as is inevitable considering the derivation of their authority. In England a somewhat similar conflict has been recognized between the health needs of a town community and the agricultural interests of the surrounding district. The *British Medical Journal* (Dec. 21, 1912) thus comments on the Milk Bill recently under discussion:

> On December 10, the president of the local government board introduced a bill to make better provision with respect to the sale of milk and the regulation of dairies in England and Wales. . . . In order to secure improvement in these particulars, the Milk Bill provides for the inspection of dairies by the medical officer of health—a duty which is already imposed on that official. We have no hesitation, however, in saying that the results of those inspections, and of the reports and recommendations which will be the outcome of them, will continue to be unsatisfactory, and for this reason: The medical officer of health is elected by, and may be dismissed at three months' notice by, the rural district council, the members of which in many instances are either themselves dairy farmers or their friends and neighbors. . . . For years past royal commissions and committees have recommended that medical officers of health should not be removable from office except with the sanction of a central authority, and we have reason to know that the urgency of this reform has been impressed on the Rural Housing Inquiry Committee, which is reporting to the Chancellor of the Exchequer, so that the government is not ignorant of this necessity and importance. Opportunity was taken on the passing of the Housing, Town-Planning, etc., Act, 1909, to give security of tenure to medical officers of health of county councils, who are far less likely to come into direct conflict with the holders of insanitary property, etc. If the government has a real desire to improve the milk-supply of the country, it will place medical officers of health of districts in a like unassailable position so long as they carry out their duties in a satisfactory manner.

The apparent conflict between the agricultural interests and the requirements of public health is not the only difficulty met by health authorities. In some instances the actual power of the local board of health has been called in question. In Massachusetts the supreme court recently decided adversely to the regulation of the Boston Board of Health restricting the sale of so-called "loose milk." The supreme court was of the opinion "that the statute under which the board assumed to act is not broad enough to give them this authority." The very same decision, however, goes on to declare that "we do not consider the question whether this regulation goes beyond the constitutional power of the legislature to enact as a statute or to authorize the board of health to establish locally."[6]

Both as regards the real power of local boards of health and as regards the overriding of local authority by state legislatures there seems ample opportunity for discussion. The present tendency seems to be for the state to assume authority over many matters previously left to local control. State commissions and state boards are appointed to exercise supervision over minute details of municipal administration. It may be questioned if on the sanitary side this may not be carried too far. The problems of sanitary administration in a large city are of quite a different nature from those in small towns or in thinly populated districts, and it is certain that general state regulations applying to the latter group will often not fit the needs of the former. Local regulation in sanitary matters which are largely dependent on local conditions would seem a reasonable exercise of the principle of self-government. The fundamental principle of home rule is violated by any state enactment which, like the Illinois law before cited, forbids the inhabitants of any city to take measures that they consider desirable for the public health. We need not have too much fear of being checked on the legal side in an attempt to adjust local and state jurisdiction. The courts will in the long run reflect dominant public opinion. In this very matter of milk regulation where conflict of authority and wasteful duplication at present exist the legislature and the courts must be made acquainted with prevailing scientific opinion, and there will be little doubt of the final outcome. In the recent decision on the cleaning of milk receptacles rendered by the Court of Special Sessions of the City of New York the recognition of the peculiar health needs of a great metropolis is everywhere apparent.

---

[5] At an interstate conference in New York City in February, 1913, delegates from eight states on the North Atlantic seaboard discussed the state control of the milk industry. Three delegates from each state representing, respectively, the State Board of Health, the State Agricultural Department and the dairy interests of the state, were appointed by each governor. The results of the conference are thus interpreted by a trade journal (Creamery and Milk Plant Monthly, February, 1913): "The theorists and the medical extremists on the governing of milk-supply were voted down . . . and the practical and common-sense view prevailed." The consequences of having an industry regulated by its "friends" are familiar to the American people.

[6] Am. Jour. Pub. Health, 1912, ii, 107.

> It does not seem that the clause that provides that anyone who has in his possession such unclean receptacles is guilty of a misdemeanor in any way conflicts with the aforesaid law, but that it is an enactment in addition to the Agricultural Law, which the board of health is empowered to make for the greater welfare of the inhabitants of a great metropolitan center. When one considers the physical conditions which surround a cosmopolis like New York City, the crowding together in small places of so many individuals; the dirt, filth and germs which are bound to accumulate in spite of most strenuous efforts; the poverty, sickness and uncleanliness of so many citizens, it is at once apparent that the greatest care must be taken in the transportation of a commodity like milk, which is daily used practically in every family, and which is without doubt more susceptible of taking up germs and scattering them broadcast than any other product. . . . The Sanitary Code in Section 183 has as its object the prevention of the creation and spreading of disease germs and pestilence in a crowded city, and the act of the defendant in carting these unwashed cans to a railroad station to be shipped in that condition is a dangerous act, and any statute forbidding such a practice is unquestionably reasonable in character.[7]

The Appellate Division of the Supreme Court of New York later affirmed this judgment with the significant remark:

> Both the statute and the ordinance are undoubtedly drastic, but the danger to be apprehended from the use of unclean receptacles for milk intended for human food is too obvious and so well known that drastic measures to prevent the possibility of such use are reasonable and justifiable.[8]

It is sometimes asserted that the authority of a city inspector ends at the city line and that outside dairy inspection or interference with milk shipments from a distance is unjustifiable. Under this head another recent decision handed down by the Court of Appeals in New York is of great importance. A dairyman outside the city of New York sued the chief of division of food inspection for damages sustained through his official action in notifying a creamery company not to include the plaintiff's milk in its shipments to the city, the officer in question having acted on the report to his department by its inspector that the conditions of the plaintiff's dairy were insanitary. The complaint was dismissed in the Supreme Court of Delaware County, and was appealed by the plaintiff with the result that the judgment is affirmed. The decision includes the following lucid and emphatic statement:

> The Department of Health of the City of New York is charged by law with the responsibility of preventing pestilence and disease in the city of New York. Its duty is to enforce all laws applicable to the preservation of human life and the promotion of health and such as relate to the use or sale of unwholesome, deleterious or adulterated food. In the faithful and efficient performance of that duty, the whole state, as well as the city, is concerned, and the department must be deemed to possess whatever power is needed to make effective the express powers conferred. . . . Of the food-supplies introduced into the city of New York, milk is one of the most important. It is now a matter of common knowledge that, if infected, it carries with it the germs or bacilli of dangerous and epidemic diseases. It is the food of the infant and it is an important element of the food of the adult. It may be infected as it comes from the cow or it may be contaminated by reason of the insanitary conditions of the dairy. Whatever, therefore, the department of health may do toward preventing the introduction of milk into the city of New York, which its officers have reason to believe is unwholesome and deleterious, is in the performance of a statutory duty. It is unreasonable to say that the department of health, in exercising such a power, renders itself amenable to the charge of exercising an extraterritorial jurisdiction. In notifying the creamery company not to include the plaintiff's milk in its shipments to the city, it was acting for the protection of the inhabitants of the city of New York, and, therefore, for local interests. There was no interference with the plaintiff's conduct of his farm or business except as he proposed to supply milk to the city of New York there was simply an embargo laid on the introduction within the city of New York of any milk not produced by him under conditions specified by the department. It had the right to exact from all shippers of milk a compliance with such conditions as would reasonably tend to a pure product for the use of the citizens, as a condition of permitting its sale in the city of New York. In exercising the supervision and in taking the preventive measures, which appear in the evidence, the department of health was properly and reasonably executing the duty imposed on it by the statute of conserving the public health; in which, as I have already observed, the state at large is equally interested with the city.[9]

The right of a municipal health department to confiscate and destroy milk not conforming to standard has been sometimes questioned, and the Wisconsin Supreme Court decision (May 12, 1913) marks the first legal test of the matter.[10] The tenor of the decision is similar to those already cited:

> The ordinance is not an arbitrary and unreasonable deprivation of property in a wholesome food, but a regulation having the purpose of and found to be necessary for the protection of the public health. The police power of the state must be declared adequate to such a desired purpose. . . . Even if the necessity of the tests be not demonstrated and the beliefs which induced them may be disputed, they cannot be pronounced illegal. . . . We agree with the court that the destruction of the milk was the only available and efficient penalty for the violation of the ordinance.

There is thus ample evidence that the courts stand ready to uphold the enforcement of ordinances and measures designed to protect the public health, and that they will support any reasonable regulation of the public milk-supply. The opinion of disinterested experts and of officials who are endeavoring to serve the public health is bound to have greater weight with the courts than the pleadings of self-interest. While no one questions that the individual should be protected from injustice on the part of the community at large, it is nevertheless true that the health interests of the community are likely to remain paramount, and that individual hardship or injury must be acute indeed if consideration for it is suffered to override the regulations deemed necessary to safeguard the public health.

[10] Weekly Bull. Dept. Health, City of New York, June 14, 1913.

Attention may be called finally to a means for stimulating a sense of responsibility in milk-dealers which has as yet been taken little or no advantage of in this country. In Great Britain, both juries and the Court of Appeal have answered affirmatively the question of the liability of milk-dealers for cases of infection traced to milk. In one instance, cited by Savage,[11] the Court of Appeal held that the sale of an article for a specific purpose carried an implied warranty by the vendor that it was reasonably fit for the purpose and that there was no exception as to latent undiscoverable defects. In another case, a question of liability was held to be unaffected by the assumption that the farmer had taken all possible precautions.

The municipal regulation of milk-supply in the United States at present seems to lack little in the way of legal authorization or of support by enlightened public opinion. Dairy inspection, bacterial control and proper grading seem to have been carried farther in this country than anywhere else. Perhaps the points in most immediate need of improvement are (1) the definition and proper control of the process of pasteurization, and (2) the adoption and enforcement of suitable milk-supply regulations in cities with less than 50,000 population.

# SEVEN CASES OF EPILEPSY IN CHILDREN

## TRACED TO SINGLE ALCOHOLIC INTOXICATIONS ON THE PART OF ONE OR BOTH PARENTS OTHERWISE TEETOTALERS [*]

MATTHEW WOODS, M.D.
PHILADELPHIA

The relation of alcoholism to epilepsy is a subject of such magnitude, so comprehensive, varied and yet so familiar, that I shall confine myself briefly to but one small section or aspect of it—not so far as I know specifically referred to by previous writers—namely, the relation that single alcoholic inebriations on the part of one or both parents otherwise teetotalers bears to the child whose genesis occurs under such condition. It has been estimated that there are about 30 per cent. of epilepsies, not including other ancestral neuropathic disorders, in which a family predisposition cannot be found. It is an attempt to explore, even if inadequately, this pathologic *terra incognita* and point out as far as possible the origin of at least a few of these that this paper is written; for there must be some cause, connected probably with progenitors, to explain the elusive 30 per cent. whose primal chronology is at present shrouded in mystery.

In the light of comparatively recent physiologic discovery connected with the temporary effect of alcohol on the system at large, pointed out perhaps first by Richardson, and since notably by Schnyder and Dubois of Berne, Switzerland, Kraepelin of the University of Munich, Martin Mayer of Heidelberg, Hellsten of Helsingfors and Aschaffenberg of Munich, it seems possible to perceive that intoxication of one or both parents at the time of conception, independently of the physical and nervous deterioration common to chronic drunkards, may make clear the causation of some of these, as it seems to have explained to me the seven cases whose histories I am about to relate. According to the observation of nearly all epileptologists, there can be no doubt in regard to the effect of alcohol in general as a frequent factor in the production of epilepsy. The difference among observers is one of degree rather than kind. Maudsley, for example, is responsible for the startling expression that "epileptics, because of drink on the part of parents, are as much manufactured articles as are steam-engines and calico-printing machines."

In regard to the rôles played by even ancestral epilepsy as contrasted with ancestral drunkenness as causes of congenital epilepsy, opinions differ but slightly, but mostly agree on the main point, that drunkenness rather than epilepsy itself is more prolific in transmitting epilepsy to offspring. For America, Dr. Spratling of the Craig Colony for Epileptics at Sonyea, N. Y., is the dissenter in regard to this point. He says that only 14 per cent. of the thousand inmates of his institution had drunken parents, while 16 per cent. had epileptic parents; but Echeverria, the first American to write a book about epilepsy, in an analysis of 572 patients, gives parental intemperance as the cause of 17.5 per cent., while parental insanity associated with epilepsy stood for but 15 and a fraction per cent. This is a remarkable statement, as it shows in Echeverria's group of 572 cases that a greater percentage of epilepsies was produced by drunken parents than by epileptic and insane parents combined.

For France, Molli has assured us that of all persons inheriting impaired nervous systems from drunken parents, from 30 to 40 per cent. of them were epileptics, and the same writer quoting from M. Hippolyte Martin, who collected a great many curious facts about ancestral intemperance and its visitation on children to the third and fourth generation, says that in 150 cases of insane epileptics at the Salpêtrière, he found that eighty-three had intemperate parents, that is, nearly 60 per cent.; and of the 2,554 children admitted to the Bicêtre suffering from idiocy, epilepsy, imbecility and hysteria, 1,053 were the offspring of drunken parents. The same writer followed to the death a number of these patients to show that no hereditary tendency other than alcoholism produced the susceptibility to convulsions.

Dejerine also said of France that "51.5 per cent. of all epilepsies in children are due to parental alcoholism and but 21 per cent. to parental epilepsy." Thus, emphasizing again, I repeat the remarkable statement of Echeverria that as far as congenital epilepsy is concerned, it is more dangerous to the prospective child, other things being equal, to have a drunken than to have an epileptic father or mother.

For Germany, Binswanger declares of epileptics "made in Germany" that 22 per cent. of them have had their origin in chronic parental inebriation, while but 11 per cent. were due to parental epilepsy.

I should not refer to these familiar, if curious, statements with regard to the ravages of these rivals in destruction—epilepsy and drink—these twin brothers I might say in etiologic iniquity—were it not for their closeness, as it were, in consanguinity to what will be said later on.

In explaining the relationship of parental drunkenness as a causative factor in the production of the disease under discussion, it has been the custom with writers on the subject to refer it almost exclusively to that state of bodily and other deteriorations brought about by chronic alcoholic excess—such as "physical wreck," "disorganization and disturbance of the nervous system," "loss of muscular equilibrium and its cause," "diseased stomach, liver, intestines," "lowering of the bodily temperature, depression and acceleration of the heart resulting in degenerative lesions," "disintegration of muscular nerve and organic tissue," "toxemias," "degeneration of cerebrospinal system," "abnormal state of the upper portion of the cerebral mass, when the mind loses, if but periodically, its controlling influence and the rational faculties give way," "the effect on nerve structure, mucous and serous membranes," "the blood and all secretions," and any or all the physical woes released from their Pandora box by inebriety.

---

[11] Savage: Milk and the Public Health, Macmillan & Co., London, 1912.

[*] Read in the Section of Psychiatry of the Seventeenth International Congress of Medicine, London, 1913.

Children whose genesis results from the union of the victims of such physical discrepancies must almost necessarily, we may think, be born with that reflex susceptibility and the like which makes them prone to epilepsy or other mental and motor disturbances; or, in other words, it would seem that offspring born as the result of the consorting of such abnormal persons must inherit a physical or nervous vulnerability not like Achilles', of the heel only, but of the whole nervous system, which but waits for the inescapable touch of the invisible hand —the special exciting cause—to develop into epilepsy or other such diseases as vasomotor spasms, chorea and allied distempers and degeneracies of the nerve centers, and that whole school of juvenile invalidisms seen chiefly in sanatoriums for the feeble-minded, idiots, imbeciles and the insane. This, then—drunkenness—is usually and properly given as the explanation of many epilepsies, especially when the family landscape presents a background of protracted intemperance.

Yet, although according to the consensus of opinion as exhibited by the authorities I have quoted, drunkenness and its consequent degeneracy explain about 35 per cent. of epilepsies, it does not at all explain the cases I am about to enumerate, for the parents of these patients were not physically degenerate; there was no history of epilepsy or other neuroses in their respective families, and they were not addicted to intemperance, or in any way enfeebled by disease or excess, except one father, who was consumptive in the last stages of the disease, living in a camp with other consumptives, and visited but on rare occasions by his entirely normal wife.

Case 1.—The child, the result of this union, at a time when the father was under the influence of liquor, was posthumous, being born six months after the death of its father, who died suddenly while mailing a letter three months after the last visit of his wife. The child developed epilepsy in its third year.

Case 2.—The patient was the child of an engineer called from home to fill an important position on a sugar plantation in Cuba. He had been a total abstainer, but before embarking for his new quarters, leaving his wife and two children behind, was tendered a farewell banquet by friends, when he got into a state as he called it of "alcoholic hilarity," the first time in his life. Nine months after his embarkation for his new post his wife gave birth to a son who developed epilepsy in his fifth year.

Case 3.—The patient was the daughter of the widow of a soldier who died in the Philippine Islands of dysentery three months after landing. His wife assured me that she never knew her husband to drink anything intoxicating until a few days before his enlistment, when he came home in a state of alcoholic excitement, after having spent the day with some soldier friends. Next day he enlisted and she never saw him again. In due time a boy was born; on the third day after its birth it went into convulsions, remaining in them for nearly two days, and since—until it came under my care seven months ago—it averaged during the eight years of its life about one grand mal weekly, with frequent attacks of petit mal, although it has had as high as six convulsions in a day.

Case 4.—The patient was the daughter of a medical man who had never tasted liquor until the night of his first intoxication. When he began the study of medicine he was married, with two healthy children. There was no family history of epilepsy or other neuroses. On the night of the commencement of his college, one of the professors, as was the custom, gave a reception to the new-fledged doctors, when he drank his first glass of wine and another and another, and promptly became intoxicated. He declares that his epileptic child, born about the regular time after this "debauch," as he called it, developed convulsions in its second year, consisting at first of but three, at intervals of a week apart, when they disappeared for two years, but returned again at periods of about one every two or three months. Of late, they have been developing with greater rapidity, showing, too, an erratic disposition on the part of the patient amounting to mild insanity.

The other three illustrations coming under my observation are already on record.[1] Two of them, in different families were traced by the parents themselves to single transgressions in the use of intoxicants. The father of one of the families afterward became a chronic inebriate and died of pneumonia following an attack of delirium tremens, but outside of that there was no trace of degeneracy in his race as far as could be discovered. The child is still living, an inmate of an epileptic colony. The wife is married again and the mother of two robust children.

These, in all probability, would have been accounted among the 30 per cent. of epileptics the origin of whose conditions would have been unknown but for pointed questionings, for the most abstemious of people may on anniversary or other occasions lapse into an intoxication not desirable to remember, or perhaps never thought of in connection with the resultant sick child.

I know no better explanation, therefore, of the advent of at least some of these unsound members into otherwise healthy families, than the one that tells that they entered while at least one of the sentinels was drunk.

This theory, then, suggested by the chapter on alcohol in Richardson's "Diseases of Modern Life," Metchnikoff's "Studies of the Blood," and the recent investigations of the German writers mentioned in the beginning of this paper will enable the physician, I think, to trace the origin of many cases of epilepsy of unknown cause back to their probable source.

Richardson pointed out long ago the changes effected almost instantly on the constituents of the blood by alcohol, and Metchnikoff since, in perhaps a more intimate study, has shown in particular its effect in producing temporary paralysis of the white corpuscles—the phagocytes.

Since alcohol, therefore, produces such important changes in all the ingredients of the vital fluid, as well as the secretions, may we not, reasoning by analogy, assert that it also influences or changes the constituents of the seminal fluid, paralyzing temporarily and otherwise altering the spermatozoa as it does the corpuscles and serum so that we might hazard the conjecture that it is not so much chronic drunkenness, as drunkenness at the time of conception, that causes the transmittal of an often overwhelming neurosis to offspring, and that at least some of these anomalies of apparently spontaneous development may be prevented by avoidance of the use of alcohol at the time of prospective procreation?

# RESULTS OF STAPHYLOCOCCUS SPRAY TREATMENT IN FORTY-TWO CASES OF DIPHTHERIA CARRIERS[*]

W. A. WOMER, A.B., M.D.
NEW CASTLE, PA.

Since diphtheria antitoxin has come into general use, quarantine of diphtheria cases is especially irksome. The patient is apparently perfectly well in a few days and the members of the quarantined family think that they are needlessly oppressed. The fact, remains, however, that although the use of antitoxin results in a speedy disappearance of all symptoms, nevertheless the diphtheria organisms may still be found in the throat, and are just as likely to infect others as they were when the patient was sick.

It is impossible to tell from the ordinary examination by culture whether the bacilli are virulent or not, and as animal inoculation is not usually possible in municipal laboratories, the quarantine is sometimes continued until the germs disappear from the throat, two or three negative cultures being required for release. This sometimes extends the period of quarantine for several weeks and it becomes a severe hardship to the family affected.

The period of time during which the throats remain positive varies with different patients and different epidemics. Nuttal and Smith[1] state that the average time during which notified cases remained positive was 31.6 days, infected healthy contacts averaging 36.4 days, ranging from seven to ninety days. In an epidemic of diphtheria in New Castle, Pa., in 1912-1913, there were 125 clinical cases and ninety healthy contacts were cultured; 80 per cent. of the clinical cases and 77 per cent. of the healthy contacts remained positive thirty days or longer. It is not known how much longer these throats remained positive, since no cultures were taken after sixty days.

It would seem, however, that the organisms had lost their virulence to a great extent since the children were permitted to attend school after sixty days even though they had positive throats. A close watch was kept of these children and it did not appear that they spread the disease.

It would certainly be very gratifying if some means could be devised whereby these throats could be freed from the diphtheria organisms, thus lessening the period of quarantine and the danger of infection.

Various antiseptic solutions have been used without much success; Loeffler stated at the Fifteenth International Congress on Hygiene and Demography that he had not found any treatment very helpful in clearing up the throats. Schiøtz[2] observed that in cases in which he had found the throats infected with diphtheria bacillus, a supervening infection with staphylococci caused a disappearance of the diphtheria organisms. Thinking that possibly the staphylococcus smothered out the other organisms, he obtained a staphylococcus culture from a healthy throat and applied it to the throat of five diphtheria carriers. The diphtheria organisms disappeared promptly and he concluded that the staphylococcus caused the disappearance.

Other workers have experimented along this line: Catlin, Scott and Day[3] report its use in twenty-two cases with apparently good results, Alden[4] reports sixteen cases with good success. Others reporting investigation are Page,[5] Lake,[6] Bell,[7] Wiener,[8] and Slack, Arms, Wade and Blanchard.[9]

Lorenz and Ravenel[10] report the use of a spray consisting of a bouillon culture of *Staphylococcus aureus* or a fresh suspension in salt solution. Seventeen patients received the treatment. In three pure carriers the results were very good. In six clinical cases in which the throats remained positive after recovery, four cleared up in one week, while in two cases the results were not so good. In eight cases treated early in the disease, four cleared up promptly, while three remained positive for twenty-two, thirty-six and thirty-nine days. Fay,[11] in a study including both the staphylococcus spray and antiseptics, did not obtain very good results from the spray. De Witt[12] reports that there is no antagonism between the two organisms in test-tubes, and in animals the results are not encouraging.

Thinking that perhaps we might derive some benefit from the use of the staphylococcus spray in lessening the period of quarantine, we used it in New Castle during the winter of 1912-1913. The spray consisted of a bouillon culture of *Staphylococcus aureus* at least twelve hours old or a fresh suspension in salt solution. Only one strain was used. This organism was obtained from the throat of a child of a family in which five other children presented positive diphtheria throats, this one alone being negative and furnishing a pure culture of *Staphylococcus aureus*. One member of the family had diphtheria, the others all receiving prophylactic does of antitoxin.

The spray was prepared in the municipal laboratory and delivered personally to the attending physician or nurse with explicit directions as to its use. They were directed to spray copiously both nose and throat three times or more each day and cautioned not to use any other form of treatment. The families were all intelligent people and anxious to use the spray to the best advantage, so that it would seem that the results should be a fair test of the value of the treatment as applied to municipal work.

The physicians and families were told the nature of the spray and asked to give a full account of its use. No one reported any untoward results.

Two classes of patients were treated: those who had showed clinical symptoms and still harbored the bacilli, and those who had not presented any symptoms but were healthy carriers.

Of twenty-two cases of diphtheria treated with the spray, five cases, or 22.8 per cent., showed two negative cultures before thirty days, while of twenty-two cases not sprayed, four cases, or 18.2 per cent., cleared up before thirty days. This would seem to indicate that the spray was not of much help in clearing up the throats.

---

[12] De Witt, Lydia M.: Preliminary Report of Experiments in the Vital Staining of Tubercles, Journal Inf. Dis., 1913, xii, 68, abstr., THE JOURNAL A. M. A., Feb. 8, 1913, p. 475.

In twenty cases of healthy carriers treated with the spray, seven cases, or 35 per cent., showed two negative cultures before thirty days, while of twenty cases not sprayed, four cases, or 20 per cent., cleared up before sixty days—not a very encouraging showing.

Of forty-two throats treated with the spray, twelve cases, or 28.5 per cent., cleared up before thirty days.

Of forty-two throats treated without the spray, eight, or 19 per cent., cleared up before thirty days.

### CONCLUSIONS

1. The use of the spray caused no unpleasant symptoms.
2. The use of the spray did not appreciably lessen the period of quarantine.
3. The preparation and distribution of the spray entails a large amount of work if there are many cases.
4. Apparently most of the carriers do not spread the disease after sixty days from the day the disease begins.
5. Public health officials could work more effectively if they had some practical method of determining the virulence of diphtheria bacilli found in the throats of carriers.

# THE DESIRABILITY OF EARLY DIAGNOSIS OF MENTAL DEFECT IN CHILDREN, AND MENTAL TESTS AS AN AID *

A. C. ROGERS, M.D.
FARIBAULT, MINN.

The physician may come in various ways in contact with mental deficiency of varying degrees, and his ability to diagnose a given case will often be taxed severely unless he keeps clearly in mind the essential nature of the condition and brings to his aid all available diagnostic means.

Every physician of experience recognizes the undirected and shifting gaze, the lack of prehensile grasp and the general failure of response to external stimuli through the special senses that indicate idiocy in the infant. He may also recognize the group of symptoms that indicate some form of primary dementia.

He is, however, aware that the great majority of children that show mental abnormality are neither idiotic nor affected with any psychosis and that their condition is not even included in the well-recognized types, usually associated with mental deficiency, such as cretinism, mongolianism, hydrocephalus, microcephalus, etc. He has little assistance from the common textbooks and he must be content to explain the condition in terms of such popular phrases as "a little queer," "rather backward," "not quite like other children," or something equally indefinite. It is not at all uncommon for a physician to tell the parents of a mental defective that the difficulty will pass away at puberty, or to recommend a course of special training with a view to restoring the child to a normal condition, overlooking entirely the essential feature of the defect.

To reduce the problem to its simplest form let us emphasize the following facts:

1. Mental deficiency is a condition resulting from *physical deficiency* or impairment in the brain and nervous system which becomes manifest during the developmental periods of infancy and childhood, and is neither curable nor outgrowable, and is not to be confused with forms of pedagogic retardation from remedial causes.

2. It is not, when uncomplicated, to be confused with insanity which represents an alienation from a normal condition usually *after mental development* has been completed.

3. It may be complicated with a psychosis or epilepsy or other disorder, functional or organic, but when this is the case, the mental retardation or degeneration naturally receives secondary consideration and is usually the result of the disease, or at least, they owe their origin to a common cause.

4. It follows from the foregoing that the diagnosis of mental defect is made by comparing the reactions of the patient to his surroundings with those of the average normal child. When a person experienced in handling mental defectives is called on to diagnose a case, he immediately seeks as complete a knowledge of the history of the activities of the child as may be necessary to make the comparison clear; the less the mental defect, the more complete the history required; the reactions in the home, on the playground and in the school form the basis for diagnosis rather than symptoms observed by casual direct examination.

Thus the problem, as ordinarily presented to the physician — and it is usually the family physician who first discovers it, or is first consulted concerning the child that is "not right" mentally—is a psychologic one. Whether or not any definite pathologic condition might previously have been discernible, it goes without saying that in the great majority of cases of this kind, as presented to the physician, no definite lesion can be discovered that accounts for the mental condition—and it is the mental condition that causes his advice to be sought—and so he is at a loss for any standard by which to make his own mental picture of the case clear, to say nothing of meeting the anxious inquiries of parents and friends with a satisfactory diagnosis and prognosis, unless there is a profound or near profound idiocy or a marked psychosis. It is here that the system of measuring intelligence comes into service, and the Binet-Simon tests afford the best means so far devised for this purpose. They are rapidly serving to standardize mental retardation and defect. They represent a system of about fifty-five procedures to which the reactions of the child give the examiner as much information concerning his intelligence as the longer and more indirect methods, which even the expert must otherwise employ. While the system is entirely empirical, it is the selected result of work with normal and abnormal children during a period of twenty years. To better appreciate their *raison d'être* and their application, one should note the following basic principles involved in the child's development.

1. Psychologists teach us that the evolution of the intellect, using the term in the sense of capacity for knowing, is completed in children at about 13 years of age or 15 years as a possible maximum. During the evolutionary period the child is growing in capacity month by month and year by year, more rapidly during infancy and at a lessening rate in later childhood until it ceases at the end of the period stated.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

2. It is quite evident from this that if from any cause, whether it be an inherited deficiency in germ cell potency, or toxic or traumatic influence during fetal life, infancy or early childhood, this evolution be interfered with, the child's mental capacity is lessened. The mental evolution may cease at an early period—or rather, it may never get under way, as in idiocy; or there may be a simple slowing down so that the child's capacity at any age below 13 is less than that of a normal child at the corresponding age, and its capacity at 13 (or at least 15) never increases. As the system of measuring intelligence enables the qualified examiner to determine the mental age of the child, it is obvious that if its development be retarded, the amount of retardation will be expressed by the difference between the mental age and the chronologic age, if the child is under 13, or 13 less the mental age if over 13.

As to reliability of tests it is unnecessary here to say more than that while there is considerable difference of opinion in regard to the relative value and proper age adaptation of certain particular tests, these are minor details. Goddard and Kuhlmann, who have done more work with the tests in this country than any other psychologists, as well as others, like Huey, Wallen, Towne, Terman and Childs, who have done enough to speak with authority, agree as to their general reliability.

As to the qualifications of an examiner, when the tests were introduced into this country by Goddard, there was considerable apprehension in regard to their use by any but expert psychologists. The fact is now conceded that this is not justified. I was at first inclined to share this view, but after observing the working of the system as applied methodically and thoroughly to over 1,500 mental defectives and on over 1,000 schoolchildren (by Kuhlmann and under his direction), and after observing the work of different teachers under training in the use of the system, I have become convinced that this is unnecessary. What is more to the point, however, Goddard, Kuhlmann and other psychologists do not consider it necessary that the examiner be a trained psychologist. He should, however, have the psychologic attitude toward the child, and should be properly trained in the use of the tests and how to evaluate the reactions to them. Some people make good examiners and others do not, with the same training. Women, other things being equal, make the best. The situation is somewhat analogous to that of the constructing engineer and the operating engineer of a locomotive. The mechanism is invented and perfected by the psychologists and they have given full instructions as to its use. The examiner must learn the technic and must have the right temperament, especially the faculty of getting the full confidence of the child and securing full and free response. The psychologists can be depended on to remedy any defects discovered in the mechanism.

Already the system is being applied in many public schools, especially in the large cities, either as a regular test for special cases or for making surveys. So much for the system of measuring intelligence.

The physician, naturally conservative, not inclined to be carried away by new "fads," may properly inquire:

1. Why should our profession employ a system of measuring intelligence which at most only deals with "symptoms."

2. Assuming that it will be of service in determining intellectual levels, how is the result to be translated into definite diagnosis or prognosis; in other words, what amount of retardation indicates mental defect?

The symptoms—the functioning of a partially developed mind—are exactly what the physician is after at that point in the history of any given case when the mental tests would be called into requisition. The arresting cause, whether it be a lack of hereditary force in the germ plasm, chemical poison, sepsis, or traumatism, has done its work and the physician is studying the patient as an imperfect human product; hence, the problem is, what is to be done for this patient? What training and development is he capable of? We all know that normal children are capable of learning to act, to think, and to inhibit action, with increasing effectiveness as they increase in age and experience, and, inversely, the amount expected of a child will be proportionately less as its age approximates birth. If, then, the child passes the age of 13 with a markedly retarded mental development, this is recognized as a defect and the intellectual level at which the development stopped will in general determine the educational capacity of the child and will be expressed by his mental age, or the age of a normal child at the time when this ability is found. Thus, these "symptoms," while not pointing to any definite cause or pathologic condition, as might be the case in a type of fever, are an index of the condition that must be known to suggest the treatment and training to be employed.

The next question, as to how much retardation constitutes mental defect, while not answerable with scientific accuracy, does not leave a margin of uncertainty that invalidates the general usefulness of the examinations. Suppose we say arbitrarily that three years' retardation at 13 indicates positive mental defect, this will leave a safe margin, as less retardation usually represents incompetence. The examiner can make a very workable table for practical use based on this assumption, and intended to apply to lower ages. Suppose the retardation be three years at 13, then we may assume for practical purposes that $^3/_{13}$ is the constant factor of retardation. At 9 years the retardation would be approximately 2 $^1/_{13}$ years and at 6 years, 1 $^5/_{13}$ years, etc. If a greater retardation is found, it simply means the use of a correspondingly larger factor and a lower mental age.

Now it is not to be understood that this means of determining the retardation at any other age than the one at which the examination is made is scientifically correct. It is only a ready method of making an approximate estimate. Psychologists have not worked out the problem of the rate of the evolution or development of mind in normal children. That is, how it varies in uniformity from birth to 13, nor is it yet ascertained whether there is a definite relation between the normal rate and the retardation rate in mental defectives.

Again, we would not expect that mental retardation from traumatic and possibly other postnatal causes, would follow any rule, because the cortical areas or nerve lines affected would obviously vary greatly. As 60 per cent. to 70 per cent. of all cases of mental defect are probably hereditary, the field for the uses of the tests is not greatly limited by this fact, and they are useful, obviously in acquired cases. Some of these cases in which the cause is traumatic, will show a sudden and complete arrest of development at the time of the accident.

Now as the higher faculties are the last to develop, it is obvious in theory and verified by experience that with one or two years' retardation even, there is usually poor judgment, lack of forethought, weak inhibition in relation to appetites, and in general, lack of capacity and resistance to cope with the social and economic condi-

reaction, uttering expressions indicative of her uncertainty as to her surroundings. She seemed perplexed as to her own identity and of her relations with her family and other members of the household. At present she vaguely recalls the state of mind at that time. She directed a number of coherent questions to the maid; but, although she received positive replies, immediately repeated these questions, each time forgetting what she had asked before.

Dr. A. D. Dryfoos attended her that evening and found her in a state of marked mental confusion. This was due largely to the fact that memory for the preceding two days was so defective that she was almost completely amnesic. Her mental processes were otherwise normal, though she was highly emotional, but controlled herself fairly well and her responses were intelligent, and thought and ideation but very slightly disturbed. In this, the psychopathologic state had two distinct components.

The doctor had occasion to speak to her about the experiences of the past summer and learned that she had forgotten the greater part of them; also that the events of the previous forty-eight hours had been apparently entirely effaced from her mind. Although she had spent the greater part of the summer at Delaware Water Gap, the name was only vaguely recalled and not associated with any experiences of her own. She could not recall that she had been in school that day, and did not recognize members of her own family, or remember the name of the maid. The temperature was not abnormal.

On the following morning Miss M. arose feeling in splendid health physically and with less mental confusion, although her memory had not been restored. That evening, when I first saw her, she had a temperature of 105. Though her mind was clear, she could not recall the events of the past two days.

The next day, the 11th, there was distinct splenic enlargement and a dichrotic pulse. An examination of the blood by Dr. Dryfoos disclosed the malarial plasmodium in numbers. The history of the case from this time was a typical tertian rise in temperature and general malaise. On these days there was marked mental confusion preceding the rise in temperature by some hours, though the amnesia was continuous long after all malarial symptoms disappeared, and even at present there is only partial restoration. The prodromal symptoms of two days' duration were characterized by partial amnesia.

These amnesias are doubtless true functional conditions, though directly of toxic origin. The case of Professor A. conclusively establishes that. The dissociation in his case was manifestly a functional one; the working of the subconscious was well shown at the moment when the patient arose to go to the telephone at the proper time to postpone an engagement which he had arranged for. Conscious or cognitive memory was suspended. We see allied states in hypnosis and in induced subconscious states.

In the case of Miss M., as in that of Professor A., dissociation was preceded by emotional upheaval. In the one case, the malarial toxin was the directly exciting factor of the dissociation, and in the other, tobacco played this rôle.

In these cases, just what significance the psychanalyst would attach to the experiences that shortly preceded the psychic symptoms, I shall not here discuss. There was effort at suppression. This is hardly relevant, however, and the dissociation can doubtless be fairly attributed to the toxic action of the exogenic poisons.

In the case of Miss M., the patient was seen by a qualified internist who regarded the case as one of typhoid, and I too was at first so impressed. The initial psychic symptoms, though of an unusual character, taken with the splenic enlargement, dicrotic pulse, high temperature and some tympanites, certainly suggested typhoid; the onset of high temperature and the symptoms just mentioned seemed to justify this; only the demonstrated presence of plasmodium made the diagnosis clear. Because of the personal history of the patient's mother, and also because of the personally more or less neurotic temperament of the patient, the essential psychic symptoms being of an emotional nature, the possibility of epilepsy or hysteroepilepsy was to be considered. To my mind this case is an extremely instructive one, especially to the internist.

Many authors describe initial delirium without fever in some of the infectious diseases, though I have not found amnesia observed as a dominant symptom. It is a question, of course, whether these psychic symptoms are due directly to the toxins or to certain changes produced by the micro-organism itself, such as multiple emboli, etc. The true infection delirium psychoses are regarded as arising from the specific toxins of typhoid, malaria, small-pox and rabies, since they are quite independent of pyrexia. In malaria, the characteristic psychosis which initiates the disease, replacing at first the fever, manifests itself in confusion, flight of ideas, hallucinations, anxiety, evanescent delusions and impulsive movements. It occurs most frequently with the quartan type.

According to some writers, the usual initial delirium of typhoid is of distinct character. It may be like that seen in malaria, or one attended by distinct and formulated persecutory delusions and by hallucinations. Amnesia is not mentioned in the cases I have seen recorded. I believe that when the usual malarial manifestations are represented by the psychic equivalent, we find a neuropathic soil.

Perointzky's findings in pernicious forms of malaria indicate the organic changes that the toxin can produce in the central nervous system. In the cerebrum and cerebellum there are marked hyperemia of the pia vessels, subarachnoid perivascular and pericellular spaces, and obstruction of the capillaries, their endothelium being swollen with masses of changed red blood-cells which slowly pass through the capillaries owing to their increase in size and decrease in elasticity, temporarily causing complete thrombosis. These circulatory disturbances lead to punctiform hemorrhages in the gray matter and at the boundary of the white brain substance and to degenerative and necrotic processes in the brain-cells. According to some writers, the cerebral symptoms are due to capillary emboli formed by parasites, as well as to the action of toxins.

Six cases of motor aphasia are reported by Mine, and Borne reports a case of trismus and one of tetany which he ascribes to the toxic action of the tertian malarial type. Bulbar symptoms are described and one case of left hypoglossus paresis, dysarthria and ataxia of the left arm. A severe case of isolated motor aphasia as a sequel to malaria in a European resident of East Africa is reported. Temporary aphasia followed each attack of the malarial paroxysm and, although the latter subsided in the course of time, the aphasia persisted. A malaria parasite thrombosis, or an embolism in the brain capillaries is assumed, producing a permanent lesion.

That the malarial toxin can give rise to disturbances in an interim during which no parasites or other malarial manifestations are evident and show a peculiarly selective site, is shown by the case described by Forli. The patient had suffered from severe malarial infection, though free from symptoms and parasites at the time of the nervous symptoms. The case is of importance because postmalarial nervous disturbances of cerebral origin are uncommon. Other etiologic factors appear to have been excluded. The onset of vertigo, vomiting, ataxia, asthenia, muscular hypotonus and nystagmus fifteen days after the last paroxysm of malaria is referred by Forli to the specific toxin. He asserts positively that he excluded mechanical circulatory disturbances as a cause.

In severe cases of malarial infection, during the Spanish-American War, I had occasion to examine at a later date some psychic manifestations that were evidently equivalents of the malarial paroxysm. These were brought to my attention during my service as U. S. examining surgeon. In those cases, as I recall them, maniacal states of weeks' or several months' duration characterized the picture. I remember that the intellectual faculties, according to histories given, were much disturbed, though the patient could give a fairly clear account of his condition after recovery.

Regis, on the other hand, says that the psychic disrbances noted in the cases of chronic malarial infection followed by amnesia; he also finds mania the preminant state. According to the same author, the psychic disturbances during the usual attacks of the malarial plasmodium actively resemble those of acute alcoholism, while the psychic phenomena of the interval are analogous to those of the chronic form.

As is well known, malarial manifestations, like those of syphilis, are prone to appear at times when there is reduction of resistance in the economy. For example, the accoucheur is often confronted with the characteristic pyrexia, etc., in women who have suffered previously with malaria. There is a depletion of the system incidental to childbearing. Again, symptoms of malarial origin obstruct the clinical picture, often after traumas, and this is especially true in regard to severe traumas of the central nervous system.

In several of the cases which I saw after the Spanish-American War in which there were profound psychic disturbances, postmalarial, there was a head trauma as a direct etiologic factor. Literature affords instances of cases of similar nature; but a review of literature indicates the paucity of recorded cases of true amnesia either in nicotin poisoning or in malarial infection.

The case of Professor A. is most unusual, and that of Miss M., if regarded as a prodromal stage of malaria, is rarer. The symptoms of tobacco intoxication, or of its essential oil, nicotin, are variously described. I shall deal only with its effects on the nervous system and, more particularly, with psychic manifestations. A pure amnesia, as in the case of Professor A., I have been unable to find described.

Experimental investigations on the effect of nicotin in the lower animals have led to positive findings in the nervous system. Vas fed rabbits for a prolonged period with increasing doses of nicotin up to 2½ grains daily. He found hemoglobin diminished in six weeks to 40 per cent., with red cells proportionately decreased, body-weight and alkalinity of blood diminished. Histologically, marked cell changes in the nervous system were demonstrated in the anterior horns, spinal and sympathetic ganglia. These findings fairly represent those generally described.

In general the familiar functional symptoms in man are sensation of pressure in the head, vertigo, somnolence, disturbed capacity for intellectual effort, abnormal moods, amblyopic symptoms, neuralgia and mydriasis, uncertainty of movement, a form of ataxia, tremor, muscular contractions, irregularity of heart action, or palpitation, emaciation, etc. I have seen bradycardia. Hyperesthesia of the acoustic is described. Aboulia, semistuporous states, insomnia, failure of memory, transitory aphasia, disturbance of judgment and agoraphobia are frequently recorded in cases of tobacco poisoning.

As to the phobias occasionally referred to as the result of tobacco intoxication, I have under observation two cases that are illuminating. Mr. H. W., after very excessive indulgence for some years, with a sudden marked increase in the daily number of cigarettes, was seized with palpitation, irregularity of heart action and precordial distress. He is a young man of about 30 and of neuropathic constitution. Withdrawal of the tobacco and rest restored him in a few weeks. On going out for the first time after his attack, he was seized with the common fear on crossing the street and soon developed the morbid apprehension characteristic of agoraphobia. One would be strongly inclined to attribute this solely to tobacco and I do not doubt that the nicotin was an exciting factor in the neurosis; but this fear neurosis continued although the nicotin had been entirely given up. Two years later I saw the patient, and psychanalysis gave the direct though remote etiologic factor, a suppressed psychic trauma. The patient recovered almost immediately through treatment by familiar psychic methods.

The aphasias are usually of a transitory character, coming on in attacks lasting from fifteen to thirty minutes, and are characterized particularly by the forgetting of names. A prolonged motor or sensory aphasia, not explained by other more evident causes, is not described.

A true and characteristic psychosis, having origin in tobacco intoxication, is fairly well established. Competent authors, such as Kjellberg, Schwartz, Frankl-Hochwart and others have observed it. Kjellberg speaks of a primary paranoid psychosis observed at the Upsala Asylum. The similarity of the symptoms points to a common etiology; they were observed only in very excessive users of tobacco. Whether or not this true psychosis can be unquestionably attributed to nicotin poisoning as a sole etiologic factor is perhaps open to question. Since, however, certain definite forms of functional psychic symptoms may be with certainty ascribed to nicotin, it is but reasonable that especially susceptible individuals, those intolerant by reason of neuropathic predisposition, should become more seriously affected by excessive and constant use of the poison. It is to be observed that the true psychosis described is invariably found in excessive and prolonged users of tobacco, and among these only when there is an unusual physical or mental strain, such as intense emotion and acute intensity in the use of the weed. The characteristic psychologic features may be divided into three stages, and these seem to be quite distinct from the various neurasthenic symptoms of nicotin poisoning. Kjellberg and Frankl-Hochwart seem to have made similar observations, and scattered through the literature are the reports of cases fitting into the groups as defined by these authors.

The patient experiences distressing sensations of weakness and incapacity for effort, and true hallucinations and suicidal tendencies follow. A prodromal stage initiates this nicotinosis mentalis and is succeeded by three distinct periods unless it terminates promptly in recovery. The prodromal stage is the one which should be recognized if the patient is to be spared a long period of mental anguish. These initial manifestations consist of general and apparently unaccountable wretchedness. There is change of disposition, and restlessness at night, finally becoming obstinate insomnia. The patient suddenly finds his work distasteful, although he struggles on; there is tendency to brood, and often to turn to thoughts of religion which later form the basis of illusions and pathologic imagery. The insomnia and psychic depression increase temporarily, and attacks of precordial distress with palpitation appear. At the end of from six weeks to three months the actual psychosis abruptly manifests itself. The patient is dominated by hallucinations; visions of a religious character appear; there are imperative concepts and fixed ideas, often associated with suicidal tendencies. There is marked depression; a feeling of great weariness and exhaustion. There are brief attacks of indefinite fear, during which acts of violence may be committed; otherwise, the patient is quiet and obedient. He speaks only on request, but gives reasonable answers to questions. Nutrition is maintained and the appetite is good. After six or seven months recovery begins, or the disease enters into a new stage. The depression changes to a state of exaltation. The patient speaks freely of what he describes as visions, such as visits of angels and other visual and auditory hallucinations. These periods usually last from two to three weeks with indefinite intervals during which the patient is discontented and gloomy and his hallucinations take a depressing form, although the patient speaks distinctly and otherwise intelligently. This stage may extend over an indefinite period; unless recovery ensues it passes into the third, the terminal stage of the disease. In this last phase of the nicotin psychosis there is a blending of the symptoms. The periods of euphoria gradually subside; the patient's mentality becomes blurred and seriously impaired. There are defects of memory, though the patient does not become indifferent to his surroundings. He becomes taciturn, speaks only on urgent request; his answers are brief, but now not always logical, though distinct and well articulated. The expression is vacant, and often there is rapid, compulsory movement.

The prognosis may be said to be favorable when the patient comes under treatment in the incipient stage and is entirely deprived of tobacco. A cure is then said to result within six months. Some authorities regard recovery as almost certain in the second stage, though a year may elapse before the pathologic periods disappear entirely.

Kjellberg knew of no instance of recovery from the third stage.

Frankl-Hochwart and others establish a remarkable number and variety of relations between the abuse of nicotin and nervous complexes not heretofore ascribed to this etiology, such as disturbances of apparently meningeal character, as well as aphasia, hemiparesis and intense and persistent neuralgia. Intermittent claudication, together with the classic nervous sequelae of nicotin abuse are included in what is described as the spinal-peripheral type. With special reference to the cerebral form, there is noted, among very excessive smokers, a premature mental weakness, a kind of senility, at an age around 50 when such changes are infrequent. There is no extreme dementia, but rather a certain reduction of the mental horizon and a distinct decrease of energy. These conditions seem to constitute a transition to the true tobacco psychosis. True disturbances of consciousness are uncommon, though a peculiar clouding of the intellect, lasting for a few moments, is described. Distressing failure of memory is recorded, while in some cases purely neurasthenic absence of mind was noted. For example: a physician, a healthy man of 31, whose first attempt at smoking began at 5 years of age and who finally became a very excessive smoker, noted suddenly, in his twenty-eighth year, that his memory for names became very deficient and he developed a tremor. The symptoms disappeared with a reduction of the quantity of cigarettes, to appear again immediately when the allowance of cigarettes was increased.

Frankl-Hochwart cites the case of a physician aged 40, also a great smoker of cigarettes, whose memory had become so defective as to lead to the commission of serious errors in practice. With the discontinuation of tobacco, a permanent cure was effected in a few months.

Some writers observe that memory defects, in greater or less degree, are likely to persist even after the disappearance of other manifestations.

# A CASE OF APPARENT FOOD-POISONING OF THE TYPE KNOWN AS BOTULISM OR ALLANTIASIS

PERCY G. STILES, PH.D.
Assistant Professor of Physiology, Simmons College
BOSTON

Food-poisoning of a narcotic type must be rare as compared with the form familiarly associated with the term ptomain. Intense pain, violent vomiting, and exhausting diarrhea—frequently attended with high fever—are the usual symptoms. Strongly contrasted with these relatively common cases are those in which there is little or no pain, no significant temperature, but a profound complex of disturbances affecting the higher nerve-centers. In a few instances a picture like this has been observed where the offending food was the mussel, a mollusc believed to develop a specific poison, mytilotoxin, under the influence of certain organisms.

Sausage-poisoning, botulism, or allantiasis is another intoxication following the eating of protein food decomposed by *Bacillus botulinus*. A few hundred cases have been recorded with mortality approaching 40 per cent. Sausage has been the cause of the great majority, but other articles of diet have been implicated. The following personal experience may be worth transcribing because of its close resemblance to Sheppard's cases[1] and because little has been said of the protracted convalescence after such attacks.

Monday, May 5, 1913, I went to lunch with two friends at a first-class restaurant. The meal consisted of minced chicken on toast, mashed potato, and coffee-jelly with whipped cream. My friends did not eat these dishes. I left the restaurant about 1:45 and returned to Simmons College, where I conducted a recitation in the period between 2:35 and 3:25. During this exercise I became conscious of a growing inertia. In the final ten minutes I held myself to my task with extreme difficulty. After a momentary sensation of flushing, I

---

[1] Bolduan: Food-Poisoning, Treat and Co., New York, 1909, Chapter 3. The cases may be briefly recalled. Three young men camping in California ate canned pork and beans. In eighteen hours they became ill and all died on the fourth day. Confusion of vision was the earliest symptom, which was soon followed by aphonia, dysphagia, and distressing accumulations of mucus in the pharynx. Muscular power failed steadily and breathing became difficult. Exertion greatly accelerated the heart. The temperature was normal or subnormal. Constipation was stubborn but there was a fair secretion of urine. To the last the mental condition was notably clear. Some of this poisonous food, given to chickens, killed nine out of twelve of those eating it.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 North Dearborn Street . . . Chicago, Ill.

Cable Address . . . . "Medic, Chicago"

Subscription price . . . . . Five dollars per annum in advance

*Contributors, subscribers and readers will find important information on the second advertising page following the reading-matter.*

SATURDAY, DECEMBER 27, 1913

On account of the large amount of space occupied by the index in this issue of The Journal, certain departments have been omitted entirely and others abbreviated.

THE INDEX

This issue of the The Journal contains the index to rrent, or sixty-first, volume of The Journal, the current medical literature which has been om week to week. The Index contains references to original articles in over two hundred of the leading medical journals of the world, including those of the principal foreign countries.

The Index consists of two parts — an author and a subject index. Under "Authors" appear the names of all who have contributed articles to The Journal or to any other medical journal listed in the current literature, as well as the names of those whose papers are abstracted in the medical society reports in The Journal. Under "Subjects" will be found complete references to all reading-matter in The Journal and references to the original articles in all domestic and foreign journals listed, arranged under the subject of the article with double entry when necessary and with numerous cross-references to facilitate the use of the Index. The figures in bold-faced type refer to reading-matter in The Journal.

The "Guide to Current Medical Literature," under which title the Index appears in pamphlet form,[1] contains, in addition, the titles of the articles listed, arranged chronologically and by journals, as in the Current Medical Literature Department. It is issued in separate form for convenience—to make it unnecessary to handle the bound volume of The Journal.

Just preceding the Index a list of the journals indexed during the past six months is given. Any foreign journal, except those starred, will be lent by The Journal to subscribers and members in the United States with the understanding that it will not be held over three days. Requests for journals should be addressed to the Library of the American Medical Association and six cents in stamps should be enclosed. This covers the average expense of mailing a journal. The addresses of the domestic journals are given, and these can be obtained direct from the publishers. No domestic journal will be lent, as these can be obtained direct from the publishers as easily and as quickly as from us.

THE GROWTH OF MEDICAL LITERATURE

In his introductory address before the annual meeting of the German Congress for Internal Medicine for 1913, Penzoldt of Erlangen offered some sound and timely advice relating to the situations created by the enormous growth of medical literature in recent years.[1] This eminent German teacher, while expressing his regret at the growing dispersion of internal medicine into a galaxy of medical "specialties" with its danger of depriving the physician of the coming decade of the helpful point of view which comes from a more comprehensive and synthetic treatment of the manifestations of disease, frankly admits that we cannot stem the tide of the prevailing tendency. One way of modifying it is to direct attention to some of the contributory influences. Among these the tremendous multiplication of published records, contributions and reviews in the field of medicine has made it necessary for the individual to confine his attention to special groups, if he would master even a modicum of what the printing-presses turn out.

How shall one account for this excessive zeal in publication? In a lecture before the Royal Institution in London, Dr. Plummer[2] bemoaned the floods of work that are being poured into journals, annals, proceedings, etc., some of it of the best, with much of it that is temporary, indifferent and bad; so that at times it seems as if some branches of science were in danger of being "smothered in the dust of its own workshop, or drowned in the waters of its own activity." We do not, nowadays, he adds, keep our ideas and scraps of work to ourselves until they are either established, or, as is more likely, dissipated; so we have a huge mass of what is called "literature," filled with many trivial, fragmentary and doubtful generalizations, many of which we have with pain and trouble to sweep into the dust-bin, Nature's blessed mortmain law taking too long to act.

It is, however, of little avail to inveigh against the current practices. We must analyze the cause of the excessive zeal for publication. Penzoldt has well said that every good physician must be an industrious investigator, for each patient brings new problems; but it is by no means essential that every detail in his modest, quiet field of research be thrust into public print. Fortunately, it is not the hope of direct monetary reward or compensation, but rather a natural, justifiable ambition and a healthy competition that calls forth the literary effort of medical men in most instances. We cannot impugn such honorable motives; nevertheless the time has come to call a halt on the endless enumeration of case histories and all of the other manifold features which characterize the ordinary contributions to the medical journals of the present day. There ought to be a wider inculcation of the principle that the index of accomplishment in the individual is not the number or diversity or prompt succession of his contributions, but rather their comprehensive spirit and fundamental excellence. If the publications of the medical profession were subjected to the same intensive and rigid critique that is applied in some other departments of literary effort, the volume of hasty output, of incomplete evidence, of uncorrelated findings and unjustified generalizations would become smaller.

---

Not alone the competition among men, but also the rivalry of journals contributes to the perpetuation of the habit of unnecessary publication. The manuscript which a critical editor with high standards of excellence rejects or advises to be modified — often to the obvious ultimate benefit of the author as well as the science involved — speedily finds its way, not into the waste-basket, but into another of the almost endless number of medical journals competing for professional favor.

Sooner or later a policy of frank, unrelenting editorial scrutiny must be adopted on a broad scale in medical journalism and scientific publications in general. The beginnings have scarcely been ventured as yet; but when a real quality standard, unyielding to the individual, unconscious of personal relationships and preferences and indifferent to offhand criticism, is once firmly put into practice, many of the abuses will remedy themselves and much of the surplus of worthless trivialities will be eliminated by a healthy growth of sentiment favorable to an abridgment of the current flood of papers. Then, in turn, the field of medical research will appear more homogeneous and be more easily surveyed than it is at present.

## THE PRODUCTION OF ANIMAL HEAT

Since Rubner's fundamental experiments[1] in relation to the long-standing problem of the source of animal heat, the conclusions which he reached regarding the equivalence of the heat actually produced in the animal body and the amount computed from the catabolism have been verified by others. Most important among these corroboratory studies, which demonstrated that the law of the conservation of energy finds a strict application in the animal body as well as in the inanimate world about us, are the widely known researches of Atwater and Benedict,[2] which established beyond a reasonable doubt that in man as well as in the carnivora the same equivalences between chemical energy, heat energy and mechanical energy obtain as elsewhere.

Although there is no reason to believe that the fundamental nutritive processes in herbivora are essentially different from those which exist in the carnivora and omnivora, the character of their digestive processes, involving as they do quite distinct types of foods along with the pronounced participation of bacterial activities, has always made direct investigations on herbivorous animals, and particularly on ruminants, appear desirable. It must be borne in mind that this group of animals experiences extensive fermentation of carbohydrates, especially in the capacious first stomach, with the production of large amounts of carbon dioxid, methane and sometimes hydrogen. Furthermore, the urinary end-products are also distinctive, including, in addition to hippuric acid, notable quantities of ammonia and more or less organic matter of unknown nature.

For some years the desired experiments have been conducted at the Institute of Animal Nutrition of the Pennsylvania State College under the leadership of H. P. Armsby. Few who have not engaged in comparable experimental work can realize the numerous sources of error and appreciate the necessary precautions which such undertakings entail. It is gratifying to note, therefore, that a total of fifty-seven experiments conducted in the past ten years have verified the expected result. The differences between the calculated and observed heat production in twenty-four hours in the total of all these numerous trials is only 0.4 per cent.—truly a close agreement.[3] The outcome is a credit to American science. It has an importance in its economic aspect as well as from a physiologic point of view. Agricultural animals are transformers of chemical energy, storing up portions of it in forms available for man's nutrition. The fundamental laws governing these transformations have now been firmly established, thanks to the energy of our American workers and the liberality with which their researches have been endowed.

## SUNLIGHT AND ORGANIC SYNTHESIS

Our English scientific colleagues, apparently mindful of the dictum that the goal of science is nothing short of the complete interpretation of the universe, have of late been busily and almost acrimoniously engaged in a discussion of the origin of life. Few of us who are absorbed in the busy occupations of an eminently practical profession stop to consider what must be, or have been, "the first stage in the evolution of organic from inorganic matter at the dawning of life in a world hitherto devoid of anything organic."[1] When, however, the possibilities of this first primeval step are presented in terms of simple reactions which all of us can appreciate, the pleasure of speculation finds ready devotees in the members of the medical profession; for when one, like a physician, is dealing day after day with the behavior of protoplasm in both its normal and its pathologic manifestations, he is likely at some time in a moment of exalted inspiration to ask himself some of these fundamental questions as to its origin.

[1] Speculations in this field are presented in an entertaining way by Moore, B.: The Origin and Nature of Life, Williams and Norgate, London, 1912.

In the vegetable kingdom we already recognize in chlorophyl, the green coloring-matter of plants, a substance capable of acting as a transformer of light-energy whereby the synthesis of organic from inorganic matter takes place. The distinguished chemist Baeyer long ago suggested that the initial stage in the synthesis of organic from inorganic matter by the green plant consists in a reaction of such simple compounds as carbon dioxid and water to produce formaldehyd and oxygen:

$$CO_2 + H_2O \rightarrow H \cdot CHO + O_2$$

The external energy which is necessary in any such transformation, because the reacting substances — carbon dioxid and water — are fully oxidized and must be reduced with evolution of oxygen and uptake of energy in what is termed an endothermic reaction, can be supplied from the energy of light vibrations. The formaldehyd is actually known to be thus formed; but in view of its toxicity it does not accumulate as such in the plant, being rapidly converted into more complex substances — possibly to carbohydrates.

Chlorophyl and its analogues are themselves highly complex organic substances and merely serve to push the inquiry a step backward. It has been necessary to search for processes in which the beginnings shall be confined solely to reactions in the inorganic world, under conditions which might exist in the world we know. The first successful attempts have consisted in the production of organic substances by the action of light on purely inorganic substances.[2] Moore and Webster,[3] in London, have now succeeded in inducing such synthesis of organic matter (aldehyd) in the presence of inorganic colloidal uranic and ferric hydroxids in very dilute solutions, the latter acting as catalysts for light-energy just as does the chlorophyl of the green plant. These inorganic catalysts are not rare, and in the words of the English biochemists, "such a synthesis occurring in nature probably forms the first step in the origin of life."

The process of evolution of simple organic substances thus having been demonstrated in an environment of sunlight and simple inorganic compounds, we can more readily picture the subsequent steps in which derivatives of more complex organic nature would arise from these with additional uptake of energy; but at this point we fancy some one asking, How about the production of the living from the lifeless organic matter? To this we must answer that there is mystery enough in the domain of medicine without attempting for the moment to penetrate into such ultimate secrets.

## THE READY RECKONER FOR THE BUSY DOCTOR

The day has not yet passed when the nostrum and proprietary manufacturer presumes to act as postgraduate instructor to the doctor—especially to the one who is not up in modern medicine. Happily, this kind of postgraduate instruction is not so common as it was eight or ten years ago, before the Council on Pharmacy and Chemistry began its work. The latest advertising scheme of this kind comes from the promoter of a "blood-stimulating" preparation (Hemaboloids, Arseniated [with Strychnia]), and is in the form of a ready reckoner for the diagnosis of pathologic sputum. The thing consists of a revolving arrow surrounded by circles containing illustrations of bacteria such as no human eye ever saw through a microscope. The physician, apparently, is expected to point the arrow to that field which resembles what he sees, or thinks he sees, in the microscope, and then, through a window in the tail of the arrow, observe the name of the organism and the disease which it produces. The device is of no value, of course, to the man who cannot tell one end of a microscope from the other; to the man who does know something, even a little bit, of bacteriology, it will appear either as an insult or a joke; in either case, after spinning the arrow once or twice, he will consign it to the waste-basket. It is hoped that there is no physician to-day so lacking in knowledge as to see any value in such a ready reckoner, so wanting in professional self-respect as to post the badge of the nostrum-promoter on his walls or so servile in spirit as to prescribe the nostrum on the basis of pseudoscientific literature provided by its manufacturer.

## THE MARRIAGE LAW IN WISCONSIN

At the last session of the Wisconsin legislature an amendment to the marriage law of the state was adopted, providing that all male persons making application for a license to marry shall within fifteen days prior to such application be examined as to the existence or non-existence of any venereal diseases. It is further required that the certificate of the physician making the examination shall show "that such a person is free from acquired venereal diseases so nearly as can be determined by physical examination and by the application of the recognized clinical and laboratory tests of scientific search." It also provides that physicians making such examinations shall be duly licensed to practice and shall be of a good moral character and scientific attainments and not less than thirty years of age. For the examination and certificate the physician is to be paid a fee by the applicant not to exceed $3. If the applicant is indigent, the examination may be made by the county physician without charge. The law further provides that "any physician who shall knowingly and wilfully make any false statements in the certificate . . . shall be guilty of perjury . . . and a conviction under this subsection shall revoke the license of such a physician to practice in this state." Physicians are thus expected to furnish certificates, knowing that any false statement therein will put in jeopardy their right to practice medicine and to earn a professional income in the state. The physicians of the state were active in securing the adoption of this law. It is safe to say that 95 per cent. of the medical profession of Wisconsin are in favor of the principle of the legal restriction of marriage to those who are physically fit to enter into such a contract. Nevertheless, strenuous opposition has arisen against the enforcement of the law among members of the medical profession. The Milwaukee Medical Society has taken a definite stand against it and its members have been quoted as saying that they will refuse to furnish certificates. Unfortunately, the first statement which appeared was simply that physicians objected because the fee of $3 was not satisfactory. Newspapers throughout the state have consequently described the situation as a "strike of physicians" for higher compensation. When the situation is understood it is seen to be entirely different from that presented by this statement. The law requires that physicians making such examinations must apply "recognized clinical and laboratory tests of scientific search." Such an examination would involve not only a physical examination of the applicant but also a microscopic examination for the detection of gonococci and a Wassermann test for syphilis. The making of these examinations requires an elaborate laboratory equipment so expensive that few physicians possess it. The customary fee for a Wassermann test alone is from ten to twenty-five dollars. Even the large commercial laboratories specially equipped for such work and making many such examinations daily charge a fee of $5. Certainly this amount must be recognized as the smallest sum for which such an examination can fairly be made. A conscientious examination for the detection of gonorrhea should also entitle the examiner to an adequate fee. Yet this law provides that physicians shall make both of these examinations as well as a physical examination for $3. This is not only absurd, but also unfair and inequitable. It places on the medical profession the financial burden of enforcing a law made solely for the public good. Physicians are required to furnish certificates and if such certificates are inaccurate, the physician's professional standing is forfeited. It is highly desirable that unfit persons or persons with communicable diseases should be debarred from marriage. Such laws are for the public good and the state should provide for their enforcement at the expense of the entire public and not at the expense of a small portion of it. If the state, for the benefit of society and future generations, sees fit to require an expensive examination as a condition for marriage, then the state should provide the means and the men by which such an examination shall be made.

## COLORADO

**Antityphoid Inoculation of National Guard.**—The general order of inoculation of members of the National Guard, now on strike duty in and around Trinidad, to guard against typhoid fever, was put into effect December 5.

**County Hospital Appointments.**—The advisory board has announced the staff for the Denver City and County Hospital for the year beginning December 1: Drs. James M. Perkins, Aubrey H. Williams and Orville D. Wescott, all of Denver, make up the board and the staff is composed of Denver physicians who give their services to the hospital.

**Conference Regarding Denver Insane.**—The overcrowded condition of the insane ward in the Denver State and County Hospital and the refusal of the state to accept patients in the state hospital caused a clash and a threatened suit between Denver and the state. The conference between Mayor James M. Perkins and Governor Ammons was followed by a promise of relief for the overcrowded ward.

## CONNECTICUT

**New Officers.**—Bridgeport Medical Society, December 2: president, Dr. J. Murray Johnson; secretary, Dr. George H. Warner.

**Hospital News.**—A fire in the Hartford Hospital, December 11, necessitated the removal of forty-two patients from one ward. No casualties occurred and the fire was quickly extinguished.——The work on the new Association Service Hospital, New Haven, will begin about February 1.

## ILLINOIS

**Personal.**—Dr. Nelson C. Phillips, Freeport, has been appointed deputy coroner in Stephenson County, vice Dr. H. E. Morrison resigned.——Dr. Walter L. Hogland, Peoria, has been elected physician of Peoria County.

**New Officers.**—Kankakee County Medical Society at Kankakee, December 11: president, Dr. George H. Lee; secretary, Dr. Charles F. Smith, both of Kankakee.——Morgan County Medical Society at Jacksonville, December 11: president, Dr. Alfred J. Ogram; secretary, Dr. George H. Stacy, both of Jacksonville.——Twin City Peru-La Salle Medical Society at Peru, December 9: president, Dr. Bert E. Fahrney; secretary, Dr. Frederick A. Guthrie, both of La Salle.

## IOWA

**Work of the State Board.**—Dr. Walter L. Bierring, president, and Dr. Guilford H. Sumner, secretary, of the State Board of Health, announce to the people of the state that the plan of work outlined by the board contemplates a sanitary investigation of every city and town line, including inspection of all public water-supplies, sewage-disposal plants and means of garbage disposal.

**Reporting of Venereal Diseases.**—Under the terms of the "black plague" law passed by the last general assembly, which goes into operation January 1, blanks have been prepared by the State Board of Health to be sent out to the physicians of the state for reports of venereal diseases. According to the law, venereal diseases are declared contagious and infectious and physicians are required to report all cases coming under their notice within twenty-four hours after discovery.

## KANSAS

**Sanatorium Nearly Ready.**—It is announced that the State Tuberculosis Sanatorium, Norton, will be ready to receive patients early in January although the entire building will not be complete until summer.

**Hygienic Teacher in Public Schools.**—The Atchison Board of Education has voted to employ a teacher of hygiene in the public schools. The teacher will be a trained nurse who will instruct the various teachers of the staff in hygiene and will also make regular periodical examinations of the school children.

**New Officers.**—Cowley County Medical Society at Arkansas City, December 11: president, Dr. Samuel J. Guy, Winfield; secretary, Dr. Benj. C. Geeslin, Arkansas City.——Allen County Medical Society at Iola, December 10: president, Dr. Omar L. Cox; secretary, Dr. Frederick L. B. Leavell, both of Iola.——Cherokee County Medical Association at Columbus, December 8: president, Dr. Robert M. Markham, Scammon; secretary-treasurer, Dr. Earl L. Parmenter, Mineral.

## KENTUCKY

**Decision Regarding Dairies.**—A very important decision has recently been handed down by the appellate court in an opinion written by Judge Hannah which gives to boards of health power to regulate city dairies. The Covington Board of Health was restrained by the Kenton circuit court from enforcing a stringent regulation of the city dairies, one of which required milk to be transported in sealed, transparent bottles. A dairyman refused to comply with this requirement and secured the injunction. Judge Hannah in his opinion said, "We are not inclined to take the narrow view that the board powers conferred on a local board of health can be exercised only when epidemics actually exist or when the cause of sickness is such as to amount to a nuisance." The opinion further said, "the most effective way to prevent disease is to remove the cause thereof," and if the local board considered this regulation essential to the health of the community, the court would not interfere unless the regulation should appear to be "unreasonable or oppressive." The court said it was neither, and that the powers of local boards of health are not derived from the city council, but from the statutes.

## MISSISSIPPI

**County Health Officers Meet.**—The county health officers of the state held a meeting in Jackson, October 28 and 29, to perfect a permanent organization for mutual benefit and for the advancement of hygiene and sanitation. Of the seventy-seven county health officers of the state, sixty-five were in attendance. Dr. Inman W. Cooper, Newton, was elected delegate to the National Federation of State License Boards.

**New Officers.**—Lauderdale County Medical Society at Meridian, December 11: president, Dr. T. D. Bordeaux, Meridian; secretary-treasurer, Dr. Gilbert F. Douglass, Chunky.——Newton-Neshoba-Winston Tri-County Medical Society, Newton, er 9: president, Dr. Daniel J. Rush, Philadelphia; sec- asurer, Dr. Sidney A. Majure, Dixon.——Hinds- edical Association at Jackson, December 9: president, ert S. Curry, Jackson (reelected); secretary-treasurer, Dr. ames H. Fox, Asylum (reelected).——Hancock County Medical Society organized at Bay St. Louis: president, Dr. Joseph W. Moody, Prentiss; secretary-treasurer, Dr. Alphonse A. Kergosien, Fenton.

## MISSOURI

**Personal.**—Dr. Luther M. Callaway, Kansas City, has succeeded Dr. Eugene Hamilton, resigned, in the school medical inspection service.——Dr. J. B. Freeman, Sturgis, is reported to be critically ill.

**Physicians on Duty Day or Night.**—The system whereby physicians of the St. Joseph's Welfare Board may be reached at any hour of the day or night was adopted by the board at its meeting, December 8.

**Hospital Notes.**—The new hospital building being erected in Springfield is to be known as the Southwestern Missouri Hospital. The association is incorporated for $20,000 and the board of directors is made up as follows: Archibald A. Low, president; Dr. Thomas O. Klingner, vice-president; Dr. David U. Sherman, secretary and treasurer and Dr. Moses C. Stone Wellesley and George D. McDaniel.——The Sisters of the Immaculate Conception of Marysville have purchased a tract of land in Hannibal upon which a hospital will be erected at a cost of $30,000.

**New Officers.**—Polk County Medical Society at Morrisville, December 13: president, Dr. R. Lee Russell, Humansville; secretary, Dr. J. F. Roberts, Bolivar (reelected).——Green County Medical Society at Springfield, December 12: president, Dr. George B. Lemmon; secretary, Dr. Thomas O. Klingner, both of Springfield.——Marion County Medical Society at Hannibal, December 5: president, Dr. Isaac E. Hill; secretary-treasurer, Dr. John J. Farrell.—Audrain County Medical Society at Mexico, December 3: president; Dr. Fred Griffin; secretary-treasurer, Dr. Harry W. Gibbs.——St. Joseph-Buchanan-Andrew Medical Society at St. Joseph, December 3: president, J. Bansbach; secretary, Dr. William F. Goetze.—— nty Medical Society at Trenton, December 3: John M. Stone, Laredo; secretary, Dr. Ola R. ——Jackson County Medical Society at Kansas r 2: president, Dr. Richard L. Sutton; secretary the bulletin, Dr. H. Louis Hess, both of —Pike County Medical Society at Elsberry, Dr. Ezekiel M. Bartlett, Clarksville: eeling, Elsberry.

### Louis

**Medical Library.**—The medical n by his uncle of the same name has been devised to the Worcester (Mass.) District Medical Society in memory of his uncle.

**Dispensary to be Closed.**—The hospital board has announced that the City Dispensary, Branch Number 3, will be closed January 1, and that the physicians and attendants will be transferred to the Central Dispensary where there is more need for their services.

**Personal.**—Dr. C. W. Bassett has resigned as assistant police surgeon.——Dr. Robert E. Graul is reported to have been awarded a verdict of $6,000 damages against the United Railroad Company for injuries received in a street-car accident, March 12.——Frank E. Chapman has succeeded Dr. Wayne Smith as superintendent of the City Hospital.——Dr. Christian H. Diehl has purchased the farm on which the Shannon County Cave is located.

## NEW YORK

**New Officers.**—Dunkirk and Fredonia Medical Society at Dunkirk, December 10: president, Dr. Walter H. Vosburg; secretary-treasurer, Dr. William J. Sullivan, both of Dunkirk.——Medical Society of the County of Rensselaer at Troy, December 9: president, Dr. Hermon C. Gordinier; secretary, Dr. John J. McShane, both of Troy.——Wayne County Medical Association at Lyons, December 9: president, Dr. Ethan A. Nevin, Newkirk; secretary-treasurer, Dr. Major A. Vedder, Lyons.——Wellsville Medical Club, organized December 10: president, Dr. Francis E. Comstock; secretary-treasurer, Dr. R. M. Eaton.——Onondaga County Medical Society at Syracuse, December 9: president, Dr. I. Harris Levy; secretary, Dr. Henry B. Doust, both of Syracuse.——Rockland County Medical Society at Haverstraw, December 3: president, Dr. J. William Giles, Nyack; secretary, Dr. Ralph De Baun, Congers.

**Alienists Urge New Crime Law.**—The committee of the Bar Association on the commitment and discharge of the criminal insane, which was appointed last January, has sent to the justices of the supreme court and to the district attorneys throughout the state opinions of alienists on the advisability of a change in the laws affecting the verdicts of insanity and criminal trials. The proposed change is intended to enable juries where a defense of insanity is made to render a verdict of "guilty, but insane," rather than the present "not guilty on the ground of insanity." The plan under the new verdict is to have the defendant sentenced to a state asylum for the criminal insane "until such time as in the opinion of the governor on an application for pardon he may be set free with safety to the community." The committee states that the proposed amendment has been in operation in England for thirty years and seems to have worked well. Opinions on this proposed change have been expressed by Dr. Orville J. Wilsey of the Long Island Home at Amityville; Dr. James V. May, Albany, of the State Hospital Commission; Dr. Arthur W. Hurd, superintendent of the Buffalo State Hospital; Dr. Austin Flint and Dr. Allen McLane Hamilton of New York.

### New York City

**Preventorium Report.**—At the annual meeting of the Tuberculosis Preventorium for Children, December 5, Mr. Marcus M. Marks, president-elect of the borough of Manhattan, resigned. He announced that the institution which is located at Farmingdale, N. J., was running with smoothness and efficiency and there was a balance of $19,988 in the treasury, of which $3,000 is to be used to complete the first half of a new school building. Dr. Herman M. Biggs was elected president of the institution.

**American Museum of Safety Awards Medals.**—The annual meeting of the American Museum of Safety was held December 12. The Travelers' Insurance Medal went to the New York Telegraph Company because of the steps it had taken to protect employees, chiefly the women workers. The Louis Livingston Seaman medal, awarded for progress and achievement in the promotion of hygiene and the mitgation of occupational diseases went to the United States Steel Corporation. The General Electric Company of Schenectady received the Rathenau medal for the best device or process in the electrical industry for protecting life and health.

**Extension of the Pasteurization Provision of the New York Milk Ordinance.**—The Board of Health of New York has amended the sanitary code and rules and regulations for the sale of milk, requiring the pasteurization of Grade B milk which was formerly permitted to be sold for certain purposes without pasteurization. This extends the requirements of pasteurization to all milk now used in the city except certified milk and similar special grades. This action followed the study of an epidemic of typhoid fever in the city which was traced to Grade B milk sold in restaurants under the provisions of the ordinance which allowed such milk to be sold raw for drinking purposes only when so labeled.

**Medical Charity Faces Deficit.**—The Hospital Saturday and Sunday Association in its annual report issued December 1 states that during the fiscal year which is closed, the expense of maintenance of its forty-seven hospitals was $4,952,309, an increase of $382,441 over the year before. The receipts of the hospitals during the same period were from income $2,160,957 and from endowment $1;023.159, leaving $1,749,193 to be raised by voluntary contributions. The income of these hospitals for the last year was $18,706 less in payments from patients, $25,657 less in payments from the city for public charges and $21,890 less from endowment as compared with the year before. During the year a staff of 2,047 nurses in addition to hundreds of physicians took care of 105,669 bed patients, while in the dispensary 507,277 cases were treated with a total of 1,673,679 visits.

**Clean Milk Bottle Ordinance Sustained.**—The provision of the sanitary code of the city of New York which makes it a misdemeanor "to receive or have in possession" any receptacle used in the transportation or delivery of milk or cream which has not been washed immediately after emptying, has been sustained by the highest court of the state of New York. It has been construed as violating no constitutional right and is within the police power of the state. The duty of cleansing the receptacle is cast first on the person who empties it. If he fails to perform this duty then it extends to any person into whose possession it falls. Certain drivers of a milk company had left unwashed milk cans on the platform of a railway station and the company was prosecuted for violation of the ordinance. The case was first tried in the Court of Special Sessions and the defendant was found guilty. In two appeals to the higher courts the judgment was affirmed.

## PENNSYLVANIA

**Recent State Board Regulation.**—Under the authority given the state board by the act of assembly, approved April 27, 1905, rules and regulations have been promulgated by the board forbidding the use of common drinking cups unless boiled or disinfected after each use, forbidding the use of common towels, forbidding the use of a common brush by barbers unless disinfected after each use and providing that eating and drinking utensils in public eating places shall be thoroughly cleansed after each individual use. Impetigo contagiosa and scabies have been made reportable diseases, as has also ophthalmia neonatorum, by a separate act, approved June 5, 1913.

### Philadelphia

**To Unite City Hospitals for Efficiency.**—Representatives of fifty-five hospitals met in the office of Chief Vogelson, City Hall, on December 11, to plan the adoption of an efficiency program for the hospitals and dispensaries of the city. A $7,000 fund is to be raised for the purpose of making an "efficiency" study of the whole hospital situation. According to Mr. F. W. Leporin, an efficiency engineer of New York, the fifty-five hospitals of Philadelphia cost each year for maintenance about four million dollars, and he estimated that the efficiency plan would save these institutions about two hundred thousand dollars a year. To bring this about, which means eliminating duplication of hospital work, an efficiency engineer would be employed to outline and chart the proper organization and management of the Central Record Bureau with subdivisions covering general efficiency departments, accounting bureaus, office methodizing departments, purchase, testing, and employment bureaus. The result of his work would be the organization of a general efficiency commission which would cooperate with the several hospital efficiency committees. Dr. Joseph S. Neff, director of Public Health and Charities, presided.

## WASHINGTON

**State Board Election.**—The State Board of Medical Examiners at its meeting in North Yakima, November 30, elected the following officers: president, Dr. R. P. Smith, Seattle; vice-president, Dr. J. L. Walker, Sunnyside; secretary, Dr. Conrad N. Suttner, Walla Walla, and treasurer, Dr. A. L. Nelson, Spokane.

## WEST VIRGINIA

**Personal.**—Dr. E. W. Strickler, Fairmont, has recovered and resumed practice.——Dr. A. U. Weinberger, Wheeling, has been appointed a member of the staff of the Ohio Valley Anti-Tuberculosis League Dispensary.

**Health Officers Convene.**—The first meeting of the State and County Health Officers of West Virginia with the State Board of Health was held in Parkersburg, November 28. During the earlier part of the day a school of instruction was held and in the evening there was a general meeting at which the president and secretary of the board and others delivered addresses. The next school of instruction is to be held in Charleston in April, chiefly for the benefit of the health officers from the southern tier of counties in the state.

**State Hygiene Laboratory Established.**—At a conference between the governor and the West Virginia State Board of Health, it was decided to establish a hygienic laboratory in connection with the School of Medicine of the University of West Virginia, Morgantown. An appropriation was set aside for equipment and for salaries of the necessary laboratory men. An important feature of the laboratory will be the study and prevention of contagious diseases. Examinations will be made free of charge for physicians and health officers in case of suspected tuberculosis, diphtheria, typhoid fever, gonorrhea, anthrax, trichinosis, etc. Chemical and bacteriologic examinations of water and milk will also be made. Vaccines will be prepared and research work and classes in public health will be conducted. The officers of the board are: president, Dr. William W. Golden, Elkins; secretary, Dr. Samuel L. Jepson, Wheeling; director, Dr. John N. Simpson, Morgantown; chief pathologist and bacteriologist, Dr. Aaron Arkin; chief chemist, Dr. A. L. Whitehill, and pharmacist, Dr. W. H. Schultz.

## WISCONSIN

**Health Budget Cut.**—The Milwaukee Board of Estimates, after making a cut of $50,000 in the health department estimate for 1914, has still recommended the appropriation of $29,000 more than was asked for in 1913.

**Would Separate Inebriates, Epileptics, Idiots and Insane.**—In the biennial report of Dr. Charles Gorst, superintendent of the Mendota State Hospital for the Insane, he recommends the establishment of state homes for inebriates and a state colony for epileptics, and, furthermore, that idiots and inebriates should be confined in county institutions.

**Sanatorium News.**—By a vote of twenty to twelve, the Board of Supervisors of Sheboygan County decided against the appropriation of $25,000 for a county tuberculosis sanatorium.——The Racine County board has appropriated $12,000 a year for the support of its sanatorium known as Sunnyrest.——The Tuberculosis Sanatorium for Outagamie County was recently opened. The institution is on the river bank near Kaukauna and has accommodations for twenty-four patients with sun parlors and other requisites.

**Eugenic Marriage Law Makes Trouble.**—The marriage law which goes into effect January 1 provides that male applicants for marriage licenses be required to show health certificates showing them to be physically fit for matrimony. The law also stipulates a fee of three dollars for the necessary certificate. As this certificate includes a Wassermann test, which in itself commands a fee of from five to ten dollars, physicians are making earnest protests and many say that they will refuse to make the examinations and issue the certificates required under the law.

**Medical Aid for Traction System.**—The Milwaukee Electric Railroad and Light Company has arranged for the benefit of its employees to reorganize its medical service. Under this rearrangement, Dr. Charles H. Lemon will have charge of the central district, with headquarters in the Public Service Building; Dr. E. W. Miller will be in charge of the southern district with headquarters at the National and Kinnickinnic stations, and Dr. W. H. Owens will be in charge of the northern district with headquarters at the Farwell and Fond du Lac stations. Under this arrangement it will be possible for the employees who need medical aid to reach the physician far more promptly than under the old system.

**New Officers.**—Milwaukee County Medical Society, December 13: president, Dr. Dennis J. Hayes; secretary, Dr. Daniel Hopkinson, both of Milwaukee. The society, by vote, has refused to make the examination required by the new hygienic marriage law.——Kenosha County Medical Society at Kenosha, December 10: president, Dr. Curtis H. Gephart; secretary-treasurer, Dr. Albert J. Randall, both of Kenosha.——Dane County Medical Society at Madison, December 9: president, Dr. Thomas W. Tormey; secretary, Dr. Frank S. Meade, both of Madison.——Waukesha County Medical Society at Oconomowoc, December 5: president, Dr. Walter S. Wing, Oconomowoc; secretary-treasurer, Dr. S. Breck Ackley, Waukesha.——Racine Physicians' Business Association, December 4: president, Dr. Walter S. Haven; secretary, Dr. George W. Nott.——Wood County Medical Society at Marshfield, December 3: president, Dr. Victor A. Mason; secretary-treasurer, Dr. James B. Vedder, both of Marshfield.

## GENERAL

**Otologists to Meet at Atlantic City.**—Dr. John B. Ray, secretary of the American Otological Society, announces that the annual meeting of the organization will be held at the Hotel Chelsea, Atlantic City, N. J., May 27 and 28, 1914.

**Medical and Surgical Exhibit at Panama Exposition.**—Among the medical exhibits at the Panama Exposition in San Francisco will be a complete demonstration of the methods employed under the directorship of Col. W. C. Gorgas in the sanitation of the Canal Zone during the construction of the Panama Canal. This should prove a valuable educational feature to the physicians and sanitarians as well as to the public visiting the exposition.

**Tri-State Meeting.**—The tenth annual meeting of the Tri-State Medical Society of Arkansas, Louisiana and Texas was held in Texarkana, December 10, and the following officers were elected: president, Dr. Preston Hunt, Texarkana; vice-presidents, Drs. Joseph P. Runyan, Little Rock, Ark.; Thomas B. Allison, Redwater, Tex., and Joseph E. Knighton, Shreveport, La.; and secretary, Dr. Jacob M. Bodenheimer, Shreveport (reelected for the sixth term).

**American Medical Men of Vienna Meet.**—On November 26, the American Medical Association of Vienna celebrated Thanksgiving Day by a banquet at which Professors Lorenz, Alexander Fuchs and Politzer were the speakers representing the University of Vienna. Dr. John W. Summers, Walla Walla, Wash., presided as toastmaster. About one hundred and fifty American physicians with their wives were present, and in addition many of the American colony of Vienna.

**Ambassador Entertains.**—The American Ambassador and Mrs. Penfield gave a Thanksgiving Day banquet to Americans residing at present in Vienna. The American Medical Association of Vienna was represented at this dinner by its president, Dr. H. T. Tangeman, Cincinnati; Vice-President and Mrs. J. W. Summers, Walla Walla, Wash.; Capt. M. A. Delaney, U. S. Army, military attaché; the secretary, Dr. J. M. Myers, Chicago, and the treasurer, Dr. John J. Sullivan, Lawrence, Mass.

**Bequests and Donations.**—The following bequests and donations have recently been announced:

Medical Department of the University of Cincinnati, a bequest of $25,000 to the chair of medicine by the will of Mrs. Jeannette Moss.

Bethesda Hospital, Cincinnati, Maternity Ward, a donation of $2,000 from "an Illinois friend."

Dr. Melvin G. Overlock, Worcester, Mass., as trustee, the income of $25,000 for the anti-tuberculosis fight in Worcester and vicinity by the will of Persis G. Boynton, Worcester.

Children's Hospital, Philadelphia, $60,000, and Germantown Hospital $5,000, by the will of Mary H. Russell.

Jewish Charitable and Educational Union, St. Louis, an increased donation of $7,000 by the directors.

Philadelphia Home for Incurables, a donation of $7,500 to maintain a free bed in the cancer annex of the institution, by George W. Nevil.

## VIENNA LETTER

*(From Our Regular Correspondent)*

Vienna, Dec. 1, 1913.

### Health Statistics

An interesting report on the number of cases of infectious diseases has been published recently in connection with the new public health act. This law stipulates the payment of a sum of 50,000 kronen ($10,000) by the government to the "union of Austrian medical councils" for the purposes of old-age pensions, orphans' grants, and the like, being a recognition of the unpaid services rendered by the medical profession to the general health. It is, as it were, an equivalent to the fees for notification of infectious diseases paid in some countries. In order to divide up this sum in proportion to the services rendered, it was decided to ascertain the number of reports of such cases in the different districts. Thus, in 1910, the number of practitioners in Vienna amounted to 2,382 men. The average number of notifications of infectious cases within the last ten years made by them was 32,265; the population in 1910 was 2,004,939. In Bohemia there were 2,670 doctors, who reported 103,236 cases; the population was 6,730,000. In Tyrol, with nearly a million inhabitants, the 571 doctors reported 15,820 cases. In the whole of Austria, with a population of over 28,000,000 and 10,498 doctors, the yearly average of notifications was 421,000, or less than 2 per cent. It is interesting to note that the proportion of infectious diseases to the population is fairly constant in all districts and does not vary much all over the empire; but the work done by the doctors is much heavier in districts in which the relative frequency of infectious diseases is low (rural or mountainous districts). These districts will get a larger share of the above-mentioned sum.

### A Strike of Medical Students

The medical students in Vienna have resolved to organize a strike as a sign of their dissatisfaction with the present system of examination. Up to a short time ago the students need not fail in their studies, even if they did not pass the examinations. They were allowed to repeat the examination within from three to six months and they could also choose the year or half-year in which they wanted to be examined. Now they are obliged, by the new regulations, to pass the severe examinations in a short time within each other—most within six weeks—and if a student has permitted more than a year to lapse between his first examination (on biology and anatomy) and his last one (on gynecology and ophthalmology), he has to repeat the first-named two subjects. Also, those students who have to serve with the army are now worse off than before in several respects. The regulations come into force just now, and the students in the fourth and fifth years who have hitherto been studying on the old system, are chiefly affected by them. They tried all means to avert the difficulties but as all endeavors were useless, they organized a strike in which all students supported them. The ministry of education will have to do away with at least the worst grievances, otherwise a general prolonged standstill of the teaching may be expected.

### Infant Mortality and Stillbirths in Austria

The official figures dealing with the mortality of infants in this country show with an interesting and instructive exactness the beneficial influence of prolonged wet-nursing on the expectation of the life of children. In those districts in which it is the custom to give the babies the mother's breast, there died out of every hundred infants born alive, between 16 and 17 within the first year of life, while the figure for infants living only one month or under was between 6 and 7. In other districts where breast-feeding is soon stopped (from 1 to 5 months) the number of infants dying within twelve months was from 18 to 23, while the number of those dying in the first month of life was about the same as in other districts (from 6 to 8). The effect of mother's milk is thus clearly illustrated. The figures for the whole of Austria are 20.5 dying within the first year and 7.9 within the first month of life. All these figures are an average for the last five years. It is also significant that in districts with old customs, stillbirths were rather few. Out of a thousand births, from 9 to 15 were stillbirths, while in districts in which there are industries or where modern life has caused change of habits, the figure was from 20 up to 41 per thousand. For Austria as a whole the figure stands at 25.2. Poverty affects the death-rate only when the wife (or mother) has to earn a wage besides doing her housework, while it loses its otherwise deleterious influence on the offspring, at least for the first part of life when the mother can nurse her baby with its natural, not with artificial, food. Anyhow there is noticeable a constant decrease of the fertility of our population. Families with more than five living children under 10 years are becoming rare now. In the "large" families the youngest children are at present more than 15 years old. It is due to the difficulties of modern life which in this country have existed since about the year 1900.

### The Fight between Krankenkassen and Doctors

The conflict between the sick-clubs and their physicians has lasted now over a year and it seems that the latter will carry their own and win. As the "clubs" are bound, by law, to procure medical help for their members or to give them an equivalent for it in cash, the member paying the doctor himself, they selected the latter method, not finding enough doctors willing to work on the old terms. The clubs have discovered that the payment of the members cost them much more than they spent formerly on doctors, and such an argument on the pocket is most convincing. The doctors, however, have found out, too, that the clubs have to come to terms and now it is quite sure that their services will have to be paid for at a more remunerative scale. The principal difference now between the clubs and the doctors is the demand, by the latter, that the "black-leg" practitioners—those who have accepted appointments pronounced boycotted—should be dismissed. The clubs refuse, being bound by contracts, but the organization of the profession must keep up this demand, for future conflicts. It is quite certain that an understanding will be arrived at in a short time.

## Marriages

William Long, M.D., St. Paul, Minn., to Miss Mary Vail Tisdale of Slayton, Minn., at Minneapolis, December 10.

Louie Ethlyn Vandervoort, M.D., to Mr. Henry Martin Stegman, both of Battle Creek, Mich., November 25.

Thomas P. Fore, M.D., Brookfield, Mo., to Miss Bess Griffith of Grand Island, Neb., at Kansas City, December 8.

Thomas John Murray, New London, Conn., to Miss Helen G. O'Rourke of Waterbury, Conn., November 18.

Bedford E. Love, M.D., Roxboro, N. C., to Miss Julia Louise Cole of Danville, Va., at Roxboro, December 3.

John Edward Clark, M.D., Streator, Ill., to Miss Evelyn Meyer Brogley of Butte, Mont., December 3.

Clarence A. Peaslee, M.D., to Miss Frances D. Hobson, both of Bath, Me., in Portland, December 9.

Esick Albert Aisenstaedt, M.D., Chicago, to Miss Ethel Ferrell of Nashville, N. C., December 9.

David Earle Lowe, M.D., New Salem, Pa., to Miss Ella Brooke of Uniontown, Pa., December 12.

Roy Frederick Breeden, M.D., to Miss Marjorie Jane Marne, both of Chicago, December 9.

Herman C. Tietze, M.D., to Miss Maude O. Buxton, both of West Salem, Ill., October 29.

## Deaths

**John Giles Cecil, M.D.** Hospital College of Medicine, Louisville, 1879; one of the best known practitioners of Louisville; died at his home, December 12, from heart disease, aged 58. He was born in Monticello, Ky., the son of a wealthy planter and banker, and received his academic training at Princeton University from which he was graduated in 1876. After a service as intern in the Louisville City Hospital and an extensive postgraduate course abroad, he began practice in Louisville. Dr. Cecil was a Fellow of the American Medical Association, president of the Kentucky State Medical Association in 1907, professor of medicine in the University of Louisville and since the merger of the medical school, a member of the executive committee of the faculty and trustees. He was also medical director of the Inter-Southern Life Insurance Company and for three years had been president of the Louisville branch of the Young Men's Christian Association.

**Orlando P. S. Plummer, M.D.** Jefferson Medical College, Philadelphia, 1857; a member of the Oregon State Medical Association and one of the first telegraphers to take messages by sound; a surgeon of volunteers and army telegrapher during the Civil War; for nearly fifty years a resident of Portland, Ore.; for several years superintendent of the Pacific division of the Western Union Telegraph Company; one of the first members of the faculty and first dean of the Medical Department of Willamette University, Salem; a member of the first state board of medical examiners; for two terms a member of the state legislature and twice member of the city council of Portland; died at his home in Hillsdale, Ore., December 7, aged 77.

**Abiel Ward Nelson, M.D.** Harvard Medical School, 1861; surgeon of the Eighty-Eighth Massachusetts Volunteer Infantry during the Civil War; a member of the Connecticut State Medical Society; surgeon-general of the National Society of Mayflower Descendants; one of the organizers of the New London City and County medical societies; trustee of the Manwaring Memorial Hospital; died at his home in New London, December 6, aged 77.

**Rollin Clayton Ward, M.D.** Harvard Medical School, 1870; a member of the American Medical Association; a veteran of the Civil War; formerly a practitioner of Northfield and Shoreham, Mass., and East Orange and Princeton, N. J.; died at the home of his niece in St. Johnsbury, Vt., December 9, aged 75.

**Caleb M. Lowder, M.D.** Medical College of Indiana, Indianapolis, 1881; a member of the Indiana State Medical Association; died at his home in Dugger, Ind., December 10, from heart disease, aged 55.

**John Walter Staples, M.D.** University of Vermont, Burlington, 1880; a Fellow of the American Medical Association and once president of the New Hampshire Medical Society; a trustee of Proctor Academy, Andover, and secretary of the Daniel Webster Birthplace Association; died suddenly in his private hospital, Sanborn Hall, Franklin, N. H., December 11, from cerebral hemorrhage, aged 58.

**Zaccus Prall Boyer, M.D., Jr.** University of Pennsylvania, Philadelphia, 1881; aged 57; formerly chief surgeon for the Philadelphia and Reading Railroad and located at Pottsville, Pa.; for the last nine months a practitioner of Philadelphia; fell while descending a stairway from his office, December 6, fracturing his skull, and died before he could be taken to a hospital.

**Albert Blodgett Weymouth, M.D.** Bellevue Hospital Medical College, 1863; for many years a medical missionary of the Protestant Episcopal Church at Lahaina, Maui, Hawaii; honorary canon of St. Andrews Cathedral, Honolulu; a Fellow of the Royal Horticultural Society; died at his post in Lahaina about October 27, aged 74.

**William Mackall Wheeler, M.D.** University of Virginia, Charlottesville, 1895; Surgeon and Lieutenant Commander, U. S. N. with station at the Marine Barracks, Norfolk Navy Yard; a Fellow of the American Medical Association; died in the U. S. Naval Hospital, Washington, D. C., December 14, aged 39.

**J. T. Parker, M.D.** Medical College of South Carolina, Charleston, 1861; a Confederate veteran; formerly of Buena Vista, Miss., but since 1895 a resident of Waco, Tex.; died at the home of his daughter in the latter city, November 27, from cerebral hemorrhage, aged 76.

**Charles Stuart Murray, M.D.** Trinity Medical College, Toronto, 1873; L.R.C.S. Edinburgh, 1877; for seven years surgeon on transatlantic steamers and then for a short time a practitioner of Toronto; died at his home in that city, November 6, from pneumonia, aged 63.

**William Lewis Judkins, M.D.** University of Pennsylvania, Philadelphia, 1894; of Barnesville, O.; a member of the Ohio State Medical Association; died in Mt. Carmel Hospital, Columbus, O., from shock following an operation for ethmoiditis and meningitis, December 9, aged 45.

**Sherman Van Ness, M.D.** College of Physicians and Surgeons, New York City, 1883; of Chatham Center, N. Y.; in 1889 coroner of Columbia County; died in St. Peter's Hospital, Albany, N. Y., December 2, a week after an operation for appendicitis, aged 54.

**John H. Engles** (license, Oklahoma, 1908); said to have been a practitioner for forty-one years; died at his office in Newkirk, December 9, from the effects of a gunshot wound to the head, self-inflicted, it is believed, with suicidal intent, aged 66.

**Lyman Hall, M.D.** Drake University, Des Moines, Iowa, 1902; a member of the Iowa State Medical Society and for eighteen years a practitioner of Spring Hill, Iowa; died in Albuquerque, N. Mex., December 6, from cerebral hemorrhage, aged 44.

**Leonora Fletcher Lathe, M.D.** New England Female Medical College, Boston, 1886; for fifteen years assistant supreme medical examiner of an insurance fraternity; died at her home in Cambridge, Mass., December 5, from heart disease, aged 79.

**Irenaeus J. Atwood, M.D.** Rush Medical College, 1889; for twenty-seven years a medical missionary in Fen Chofu, Shansi, China; died in a sanatorium in Puyallup, Wash., October 1, from cerebral hemorrhage, aged 62.

**Jacob Walter Eleeza Karr Davis, M.D.** University of Buffalo, 1887; a practitioner of Omaha for twenty-six years; died suddenly in a street car in that city, December 4, from heart disease, aged 64.

**Norman Eugene Farewell, M.D.** Trinity Medical College, Toronto, 1897; assistant surgeon to the Brooklyn Eye and Ear Hospital; died at his home in Brooklyn, December 12, from pneumonia, aged 37.

**Thomas Marshall Huntington, M.D.** Bellevue Hospital Medical College, 1883; of Amesbury, Mass., was struck and killed by a freight train in the Newburyport station, December 9.

**James Franklin Leslie, M.D.** Eclectic Medical Institute, Cincinnati, 1900; of Waterville, Wash.; was killed in an automobile accident near that place, November 23, aged 42.

**Fitzwilliam Sargent Worcester, M.D.** Harvard Medical School, 1873; of Peabody, Mass.; died at the Joshua B. Thomas Hospital in that city, December 7, aged 62.

**Benjamin T. Gadd, M.D.** Eclectic Medical Institute, Cincinnati, 1865; of Mitchellville, Iowa; died at the home of his daughter in Colfax, Iowa, December 9, aged 76.

**William H. Ward** (license, California, 1894) a practitioner for fifty years; formerly of Des Moines, Iowa; died at his home in Long Beach, Cal., about December 10.

**James S. Morton, M.D.** University of Louisville, Ky., 1850; a Confederate veteran; died at his home in Hartford, Ky., December 8, from senile debility, aged 85.

**James Vincent Canavan, M.D.** Rush Medical College, 1894; a Fellow of the American Medical Association and first mayor of Appleton, Wis., died December 4, aged 53.

**Lee O. Rogers** (license, Iowa, years of practice, 1887); for thirty-five years a practitioner of Newton; died at his home, December 4, from heart disease, aged 69.

**Stanley L. Thorpe, M.D.** Cleveland University of Medicine and Surgery, 1882; formerly of Cleveland; died in Salt Lake City, December 7, from uremia, aged 62.

**Samuel E. Crose, M.D.** Central College of Physicians and Surgeons, Indianapolis, 1888; died at his home in Indianapolis, October 27, from pneumonia, aged 47.

**John Houston, M.D.** Manitoba Medical College, Winnipeg, 1906; of Cypress River, Man.; died at the home of his father in Starbuck, Man., recently, aged 35.

**Ham Hunter, M.D.** Ohio Medical University, Columbus, 1893; was found dead in his office in Columbus, November 30, from heart disease, aged 50.

**William Thurston, M.D.** American Medical College, Eclectic, St. Louis, 1880; died at his home in Orland, Cal., about November 26, aged 92.

**James R. L. Daly, M.D.** University and Bellevue Hospital Medical College, 1899; died at his home in New York City, November 29, aged 38.

**Samuel H. Backus, M.D.** Tulane University, New Orleans, 1897; of Pollack, La.; died suddenly at Gueyzan, La., about December 8, aged 40.

**Dugald Stewart** (license, Ontario, 1876); for more than thirty years a practitioner of Teeswater; died at his home, August 22, aged 64.

**William Bertram Arnold, M.D.** Eclectic Medical Institute, Cincinnati, 1879; died at his home in Rockford, Ill., November 23, aged 72.

**Dorsey L. Morris, M.D.** Medical College of Virginia, Richmond, 1897; died at his home in Greensboro, N. C., about November 5.

**John Lemuel Bethune, M.D.** Halifax (N. S.) Medical College, 1875; died at his home in Baddeck, N. S., September 27, aged 63.

**Edward C. Kalmerton, M.D.** Rush Medical College, 1887; died at his home in Milwaukee, October 26, from diabetes, aged 59.

**Archelaus M. Winn, M.D.** Atlanta (Ga.) Medical College, 1867; died at his home in Lawrenceville, Ga., October 25, aged 68.

**Charles A. Usilton, M.D.** Jefferson Medical College, 1882; died at his home in Philadelphia, December 3, from nephritis, aged 59.

**Nathan L. Hammer, M.D.** Physio-Medical College of Indiana, Indianapolis, 1882; died at his home in Indianapolis, October 27.

**Charles H. Sherman, M.D.** Louisville, (Ky.) Medical College, 1889; died at his home in Louisville, December 9, aged 69.

**William White Brewer** (license, Mississippi, 1882); died at his home in Lamar, September 23, from uremia, aged 85.

**Ernest Warren** (license, Oregon, 1891); of Newport, Ore.; was found dead in Portland, Ore., October 25, aged 50.

**Harvey J. Philpot** (license, British Columbia, 1894); died at his home in Vancouver, November 11, aged 80.

**Rev. John Gethin Thomas** (license, Ohio, 1897); died at his home in Lima, November 15, aged 71.

**Marion H. Jackson** (license, Arkansas, 1903); died at his home in Neely, November 7, aged 36.

**Arthur Fisher,** L.R.C.S. Edinburgh, 1880; died at his home in Montreal, December 3, aged 98.

# Correspondence

## Improved Technic for Blood-Counts

*To the Editor:*—I desire to make a few comments regarding the clinical report of Dr. Allan Eustis on an "Improved Technic for Blood-Counts: Rapid Method for Securing Exact Amount of Suspension" (The Journal, Nov. 29, 1913, p. 1984).

Although I have not seen the technic of placing the cover-glass on the counting-chamber, as recommended by Dr. Eustis, described in any book or journal before, yet it was the method in vogue at the William Pepper Laboratory of Hygiene at the University of Pennsylvania fourteen years ago.

Incidentally, I would mention the following modification of the *modus operandi* as advised in the article above referred to. The cover-glass is placed on the edge of the counting-chamber, with its edge approximately parallel with the edge of the counting-chamber. Then the tips of the forefingers are placed on the distal side of the cover-glass and the ends of the thumbs on the proximal edge of the cover-glass. While downward pressure is exerted with the forefingers, the thumbs are used to push the cover-glass across the counting-chamber. This technic is advocated, obviously, to cause all of the supposedly contact portion of the cover-glass to be closely in contact with the counting-chamber, while the two thumbs can readily push the cover-glass across the counting-chamber even though the cover-glass is in close contact.

The real object of this communication, however, is to correct one little (but important) point mentioned by Dr. Eustis, namely, regarding the size of the drop. I fear that beginners may find a pitfall in using a large drop of the blood and diluting fluid. Theoretically it would appear that the size of the drop would make no difference; but my experience has been that the smaller the drop (provided there is enough) the more easy it will be to obtain a satisfactory "mount" and the more likely it will be that we shall see Newton's rings after the first trial.

Charles Rea, M.D., York, Pa.

[The preceding letter was referred to Dr. Eustis, who replied that he did not know of the method being used in other schools and that he was positive that no one else in his section of the country had used it for the last eight years. We have also subsequently received the following letters:]

*To the Editor:*—In The Journal, Nov. 29, 1913, Dr. Allan Eustis of New Orleans gives an improved technic for blood-counts. I remember very clearly that when I was a resident physician at the Medico-Chirurgical College, Dr. J. Donald Zulick, our chief resident physician, showed me the very same technic, so that it is not original with Dr. Eustis. Nevertheless, it is a very good method and saves a lot of time.

C. H. J. Barnett, M.D., Philadelphia.

*To the Editor:*—In The Journal, Nov. 29, 1913, p. 1984, Dr. Allan Eustis of New Orleans gives an improved technic for blood-counts. This improvement was taught at Jefferson Medical College in 1904, and has been used constantly by most blood workers.

W. H. Kraemer, M.D., Wilmington, Del.

## Mizer Sanatorium

*To the Editor:*—Some time ago those in charge of the Mizer Sanatorium of this place stated to us that they wished to place the institution on a high plane and to conduct it in a strictly ethical manner. To such a degree would they conform to ethical rules that the most particular in matters of this kind would find no room to complain. With this distinct agreement on their part they were allowed to use our names as references.

Of late we have learned that even the ordinary rules of propriety have been violated by them and that these acts of unfairness to us had been going on for some time before we learned of their breach of faith with us. We at once notified them no longer to use our names in any of their advertising matter or on their stationery. It appears that before we had learned of the advantage that was being taken of our confidence, others had taken note of their unethical practices.

What we wish to do is to set ourselves right before the medical fraternity and to announce that we do not stand, and have not stood, for anything which we believe or know to be fraudulent or misleading.

EDMUND C. CARR, M.D., JESSE MCCLAIN, M.D., Coshocton, Ohio.

### Deaths from Eating Chestnuts

*To the Editor:*—In THE JOURNAL, Nov. 29, 1913, p. 2091, S. T. A. refers to the newspaper report of the death of a woman from poisoning by eating chestnuts, and asks for an explanation as to how chestnuts can be poisonous.

Aside from your answer that the matter was under investigation by the Bureau of Plant Industry, is it not possible that this patient was a subject of diabetes and that she died from coma from overindulgence in this article of diet? In the dietary for diabetes all forms of nuts are allowed *except* chestnuts, and I have strictly forbidden them to patients suffering from this disease, although diabetic patients have an inordinate craving for chestnuts at this season of the year. GEORGE J. LOCHBOEHLER, Washington, D. C.

### A Note on the Use of Ninhydrin as a Test for Peptone, etc.

*To the Editor:*—Ninhydrin works best in a strictly neutral medium. Slight acidity or alkalinity destroys its delicacy. Fluids should be made neutral before testing, litmus being used as an indicator.

S. L. CHERRY, M.D., Clarksburg, W. Va.

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

### REFERENCES TO RECENT ARTICLES ON ARTIFICIAL PNEUMOTHORAX

*To the Editor:*—Have you any later reports on tuberculous patients treated with intrapleural injections of nitrogen than the one by A. F. Lemke, THE JOURNAL, Oct. 14, 21 and 28, 1899, pp. 959, 1023 and 1077), and afterward printed in pamphlet form? I am much interested in this method and would be glad to have any information you may have on the subject.

C. W. JACKSON, M.D., Albuquerque, N. Mex.

ANSWER.—The following is a list of recent articles on this subject:

Robinson, Samuel, and Floyd, Cleveland: Artificial Pneumothorax as a Treatment of Pulmonary Tuberculosis, *Arch. Int. Med.*, April, 1912, p. 452; abstr., THE JOURNAL, May 4, 1912, p. 1398.

### PRESCRIBING FOR SYMPTOMS

*To the Editor:*—I wish to protest against the practice of prescribing for the mere symptoms of disease in answer to a correspondent as exemplified in "Treatment of Indicanuria" (Queries and Minor Notes, THE JOURNAL, Nov. 29, 1913, p. 2000). One can hardly believe it necessary to call attention soberly and critically to the simple fact that the underlying condition causing the symptom indicanuria is to be discovered, that it is this condition which is to be treated, and that it may be anything from simple stasis due to lack of opportunity to carcinoma and diverticulitis. Why [illegible] eructations," for "biliousness," for

W. A. GROAT, M.D., Syracuse, N. Y.

ANSWER.—The protest plainly comes from a not too careful reading of the question. The answer refers to the one case about which the question is asked. Indicanuria, in any case, depends on putrefactive changes and its presence for five years with, apparently, no other symptoms certainly shows that no serious condition is present, and that, in this case, putrefactive changes in the intestine constitute the "causative factor." It is gratifying that we have readers so critical as to object both to prescribing for symptoms and to the warning to look for the cause; but a practitioner is to be congratulated if the diseases he sees are so clearly marked that he is always able to discover a cause and never finds himself compelled, as in "biliousness," "indicanuria" or "menorrhagia," to follow a routine treatment of symptoms until an obscure cause can be discovered. It occasionally happens, also, that the warning that causative factors should be looked for is needed by a routine practitioner.

### PROPHYLAXIS AGAINST CARRYING INFECTIONS BY PHYSICIAN

*To the Editor:*—Can you tell me if the following procedure in visiting patients with contagious diseases is safe?

I wear a cap, gown and gloves which I carry in a separate grip. After taking them off I pour a dram or two of formaldehyd 40 per cent. solution on them and close the grip. I usually do not use them again for at least twenty-four hours. Does such a process kill the germs so that I shall not expose another patient to the disease or contaminate myself in putting on the outfit again? I know a number of men who use this method.

C. E. C., Kansas.

ANSWER.—The opinion is growing that the infectious diseases, except those known to be transmitted by insects, are spread directly from one living being to another, and that fomites play little or no rôle in their transmission. At present, however, the precaution of wearing such an outfit as that described is a proper one and indicates that care is used not to spread infection. The use of the formaldehyd solution in sufficient quantity to produce by its evaporation in the grip a strong gas would undoubtedly have a disinfecting effect; not so much, however, in the dry state as in connection with steam or vapor. Disinfection with formaldehyd or sulphur is more efficient if the articles to be disinfected are wet, as more of the formaldehyd or sulphur dioxid gas is absorbed.

### WAR ON THE RAT

*To the Editor:*—Some time ago I saw an article in the Waterville *Sentinel* entitled, "War on the Rat." I wrote them in regard to it and they answered that they thought that if I wrote you I could get the information that I wanted.

J. J. Crowe, M.D., Bangor, Me.

Answer.—The following is a list of articles on this subject:

### TOXICITY OF MALACHITE GREEN

*To the Editor:*—I have a patient who worked for several months in a broom-factory where the work necessitated his dipping his hands in the "broom-green" solution each day. After dipping the corn he assisted in placing the wet bundles of corn in the bleaching-room. In this room, lump sulphur is ignited and the corn is shut up tight until the following day when, after opening the room, he assisted in carrying this bleached corn to his place of work and had occasion to handle this bleached and dyed corn more or less the remainder of the day. This "broom-green" is known commercially under the name of malachite green, and chemically as the zinc double chlorid of tetramethyldi-para-amido-triphenyl carbinol. This man denies syphilitic infection and asserts that the perforation of his soft palate and nasal septum is caused by the chemicals and dust. Will you tell me something of the action of this chemical and give your opinion as to the plausibility of his assertion?

J. G. Baker, M.D., Mattoon, Ill.

Answer.—Malachite green has been used as a confectioner's color, and is stated by a number of authors to be non-poisonous. On the other hand, Penzoldt says:

> One hundred mm. per kilogram body-weight of rabbit, or 70 grains per 100 pounds, injected subcutaneously, caused after the third day motor paralysis and occasional cramps, which resulted fatally at the end of the ninth day.

According to Lewin:

> In the case of one workman, in contrast with others who had long been unaffected by this substance, itching, burning, inflammation and swelling of hands and feet, and formation of blisters occurred.

### INGREDIENTS OF PA-PAY-ANS (BELL)

*To the Editor:*—Please inform me if Pa-Pay-Ans (Bell) contains drug ingredients other than those stated on their printed label.

D. M. Hoyt, M.D., Philadelphia..

Answer.—An analysis of Pa-Pay-Ans (Bell) was included in the report of the Council on Pharmacy and Chemistry rejecting the product (The Journal, Aug. 14, 1909, p. 569). While the analysis did not prove the presence of any ingredient not declared by the manufacturer, it failed to find one of the constituents claimed to be present—the constituent after which the medicine appears to have been named, namely, papain.

### FREEDOM OF THE SOUTH AND SOUTHWEST FROM HAY-FEVER

*To the Editor:*—Can you inform me what regions of the West and Southwest are free from hay-fever?

C. C. Bassett, Goodland, Ind.

Answer.—We have no definite statement as to any special regions of the West and Southwest which are free from hay-fever, but in general the disease is less prevalent in that section than in other parts of the United States. Hollopeter cites Wyman and Beard as regarding that portion of the United States west of the Mississippi River as free from the disease. It is generally regarded that the disease is not found south of the thirty-fifth parallel of latitude.

### LITERATURE ON SWEDISH SYSTEM OF PHYSICAL TRAINING

*To the Editor:*—Can you refer me to some of the recent literature dealing with the Swedish system of physical training?

Wendall Davis, M.D., Washington, D. C.

Answer.—The following list contains references to recent articles on this subject:

Diller, T.: Massage and Massage Operators in City of Pittsburgh, *Pennsylvania Med. Jour.*, January, 1913.
Pope, C.: Massage, *Southern Med. Jour.*, May, 1913.
Kirchberg, F.: Massage and Graduated Exercises in Kidney Disease, *Therap. Monatsh.*, October, 1913.
Steele, M. J.: Hydrotherapy and Massage, *West Virginia Med. Jour.*, July, 1911.
Joffe, M.: Pressure Massage of Nerves, *Berl. klin. Wchnschr.*, Dec. 20, 1911.
Schule, A.: Massage of the Nerves at Their Emerging Points, *München. med. Wchnschr.*, Dec. 20, 1911.

### DOES SMALL-POX PROTECT AGAINST BOVINE VACCINATION

*To the Editor:*—Referring to the case reported by Hochheimer in The Journal, Dec. 6, 1913, p. 2089, the following may be of interest:

During 1908-1910 I was director of the Siamese government serum laboratory, and in testing small-pox vaccine before sending it out for use, I vaccinated many persons. Among those vaccinated were forty-six adults, each of whom had had an attack of small-pox during childhood. They ranged from 25 to 40 years of age, and of these vaccinations, twenty-six, or 56.5 per cent., were successful, thus showing that in a goodly percentage of cases variola in childhood does not confer immunity against vaccinia, lasting more than to middle age. The result also justified the recommendation of the Minnesota Board of Health, which would vaccinate all exposed to small-pox when not protected by either a recent attack of small-pox or a recent successful vaccination.

Ralph T. Edward, A.M., M.D., Ceylon, Minn.

THIS DEPARTMENT EMBODIES THE SUBJECTS OF POSTGRADUATE WORK, CONTRACT PRACTICE, LEGISLATION, MEDICAL DEFENSE, AND OTHER MEDICOLEGAL AND ECONOMIC QUESTIONS OF INTEREST TO PHYSICIANS

## MEDICAL INSURANCE ABROAD

Discussion and interest regarding the experiments being made in different countries for the compulsory insurance of the working classes and those employed at small salaries is increasing. In Germany and England, the medical profession is in a high degree of turmoil over the operation of the laws on this subject. In Denmark, a law has been in operation for six years. In Russia, an insurance law against disease and accidents went into effect last June. In Norway, the operation of the law dates from July, 1911. In Australia, while no law has, as yet, been enacted, the subject is one of vital interest to the medical profession there and is being freely discussed.

### CONDITIONS IN GERMANY

Germany has had a more protracted experience with compulsory insurance than any other nation, but has not, as yet, actually worked out a plan of administration which is free from serious objections. The German medical profession is at present in as marked a position of opposition to the German insurance law, as is the medical profession in Great Britain to the British law.

A general meeting of the medical profession held in Berlin, October 26, decided that after Jan. 1, 1914, the insured population of Germany, with the exception of Dresden, Hamburg and Berlin, should not receive any treatment from physicians through the insurance societies, unless these societies acceded to the demands of the physicians, or unless the government saw fit to intervene. The meeting was called by the president of the National Federation of Medical Societies, and was attended by 458 representatives of 384 medical societies, with a total membership of 21,207 physicians. The situation in Germany is a plain issue between the physicians on the one hand and the insurance societies on the other. The resolution adopted by the meeting stated clearly that there was no intention on the part of the physicians represented to refuse medical services to the members of the insurance societies as individual patients; the refusal was to treat them as members of the societies. Unless the demands of the physicians are accepted, they propose, after the first of the year, to treat each individual as a private patient and not as a member of an organization. In a word, the proposal is to go back to the original system of individual professional relations between physician and patient, without any middleman or intermediate party. The points under dispute are numerous and intricate, and are embodied in forty-four clauses which have been discussed in detail by the profession of Germany for some time past. These differences of opinion have to do with the right of physicians to representation on the administering boards of the insurance societies, and the right of patients to choose the physicians whom they prefer, the method of organization and administration of the medical boards, the handling of complaints, the appointment of medical officers and the determination of their duties, the remuneration for physicians and the periods and character of the contracts between physicians and insurance societies. This declaration of principles represents the minimum demands of the physicians. The compensation asked for is a per capita fee of 5 marks. This is not to include night visits, attendance on confinements or abortions, treatment of persons who have only a legal but no medical claim on sick benefits, or the treatment of families of insured persons. For all of these services, special arrangements are to be made.

Following the representative meeting of the general profession of Germany, the Federation of Insurance Societies not only refused to accede to the demands of the physicians, but refused to recognize the right of physicians to organize the profession for the protection of their individual rights. This situation, which reminds the American reader of the conflicts between corporations and employees, and the fight between these conflicting parties over the right of the working men to organize and the recognition of the unions, led the Berlin Medical Society to take an action which is rarely necessary, namely, to call a special meeting to discuss medical politics. On November 12, the Berlin Medical Society met in extraordinary session with Professor Orth in the chair. The leading members of the profession of Berlin strongly endorsed the stand taken by the representative meeting and pledged their support to the movement for professional independence. Professor Kraus said that the insurance societies had no right to dictate terms to physicians, or to insist on choosing physicians for patients. He advised the medical profession to remain "united and firm, so that you may be able to preserve for your profession its independent freedom." Dr. Munter declared that the scientific and economic decline of the medical profession must follow the imposition of oppressive terms of contract practice. He said that the insurance societies had formed themselves into a protective organization and that they were endeavoring to prevent any similar organization among physicians. A motion was unanimously adopted declaring that the demands of the insurance societies seriously imperiled the freedom and independence of the medical profession, and that the Berlin Medical Society pledged its wholehearted support to the medical profession in Germany.

### SITUATION IN ENGLAND

In England the situation is quite as serious, even if somewhat less tumultuous. Nearly a year's operation of Lloyd-George's insurance act has disclosed many weaknesses and difficulties in administration. The regulations governing the act are being revised and a general discussion is going on regarding the exact terms of the revision. As an illustration of the practical workings of the act, a special commissioner of the London *Lancet*, in a recent issue, writes interestingly of the situation in Derby and Derbyshire. Of the 560,129 inhabitants in Derbyshire, outside of Derby, 178,294 came under the provisions of the insurance act. Practically all of the local physicians, to the number of about 300, are on the "panel," that is, they have enrolled as desiring to treat persons under the provisions of the law. This gives an average of about 600 patients to each physician. One practitioner had about 3,000 insured persons on his list, and was responsible for the medical care of over 700 families. Difficulties regarding the payment of mileage has arisen, as well as practical problems regarding the dispensing of drugs, the filling of prescriptions, etc. One interesting result, according to the writer in the *Lancet*, is that the act is doing away with the "prescribing chemists," that is, with the practice of drug-clerks prescribing for customers. This fact is apparently welcomed by the high-grade druggists as well as by physicians. The *Lancet* says, "The custom of going to the chemist for advice, as well as for a bottle of medicine, is dying out rapidly, as the public argues, why consult a chemist when it does not cost any more to have a doctor?"

Another difficulty is malingering on the part of patients. The working man has to pay a fixed amount for medical and sick benefit. It does not cost him any more to be sick than it does to be well. With the large number of patients which the insurance doctors have to see and examine, it is impossible to make a careful examination in all cases. The friendly societies are endeavoring to prevent malingering by sending inspectors of their own to inspect cases in which they suspect deception. This has led to considerable controversy.

The bulk of the discussion at present, however, turns on the new regulations. These are most exhaustive, covering twenty-three pages of fine print of a supplement in the *British Medical Journal*, and containing detailed provisions for almost every part of the law. An explanatory memorandum summarizing the regulations, states that the new provisions do not affect the amount available for remuneration, but have to do principally with the method of calculating the number of persons for whom the physician is entitled to compensation. All sorts of difficulties have arisen regarding persons removing from one district to another, and the amount of compensation which the physicians in the different districts should receive on their account. It has been found impossible to keep an accurate register showing the total number of insured persons in any district at any one time, owing to the difficulty involved in the notification of removals and the mechanical work of correcting the registers. It has been found necessary, therefore, to adopt some plan by which the number of persons for whom the physician is entitled to compensation shall be averaged rather than directly enumerated. Considerable difficulty has also been encountered in dealing with complaints, and it has been found necessary to enlarge the powers of the committee dealing with this subject.

The general situation in England seems to be that the medical profession has gradually and under protest submitted to the new law and that it is now making an effort to secure as favorable regulations for its administration as possible. The *British Medical Journal*, in a recent issue, asserts that the insurance scheme is being made a counter in the game of party politics, and that the two dominant parties in the British House of Commons are using it as a political issue without regard to its merits. Leaders on both sides, the *Journal* says, are trying to conciliate the managers of the friendly societies. Mr. Bonar Law, in criticizing the act, said that many of the friendly societies were drifting rapidly into insolvency, that the act was having the worst possible effect on the character of the people, that the details of the act were not to be cured by amendments or regulations, and that, if his party were given an opportunity, it would appoint a committee to investigate the entire subject and to report whether it would not be possible, in the interest of the nation, to turn the entire scheme into a voluntary instead of a compulsory system.

Mr. Winston Churchill, in replying to Mr. Law, challenged his statements and asserted that it was one of the best administrative achievements of the century, although in force only two years and working for only nine months. According to Mr. Churchill there were 13,700,000 persons actually insured through 233 insurance committees, and 23,500 societies and branches. Twenty-two million visits had been made by 20,000 physicians at a cost estimated at £4,500,000 (about effect; not so much, however, in the dry state as in connection with steam or vapor. Disinfection with formaldehyd or sulphur is more efficient if the articles to be disinfected are wet, as more of the formaldehyd or sulphur dioxid gas is absorbed.

### WAR ON THE RAT

*To the Editor:*—Some time ago I saw an article in the Waterville *Sentinel* entitled, "War on the Rat." I wrote them in regard to it and they answered that they thought that if I wrote you I could get the information that I wanted.

J. J. Crowe, M.D., Bangor, Me.

Answer.—The following is a list of articles on this subject:

Creel, R. H.: The Rat, a Sanitary Menace and an Economic Burden, Reprint 135, U.S.P.H.S., July 4, 1913.
McCoy, George W.: Notes on the Bionomics of Rats and Ground-Squirrels, Reprint 94, U.S.P.H.S.
Heiser, V. G.: The Rats of Our Cities, *Pub Health Rep.*, July 25, 1913, xxviii, No. 30.

# *Medical Economics*

THIS DEPARTMENT EMBODIES THE SUBJECTS OF POSTGRADUATE WORK, CONTRACT PRACTICE, LEGISLATION, MEDICAL DEFENSE, AND OTHER MEDICOLEGAL AND ECONOMIC QUESTIONS OF INTEREST TO PHYSICIANS

## MEDICAL INSURANCE ABROAD

Discussion and interest regarding the experiments being made in different countries for the compulsory insurance of the working classes and those employed at small salaries is increasing. In Germany and England, the medical profession is in a high degree of turmoil over the operation of the laws on this subject. In Denmark, a law has been in operation for six years. In Russia, an insurance law against disease and accidents went into effect last June. In Norway, the operation of the law dates from July, 1911. In Australia, while no law has, as yet, been enacted, the subject is one of vital interest to the medical profession there and is being freely discussed.

### CONDITIONS IN GERMANY

Germany has had a more protracted experience with compulsory insurance than any other nation, but has not, as yet, actually worked out a plan of administration which is free from serious objections. The German medical profession is at present in as marked a position of opposition to the German insurance law, as is the medical profession in Great Britain to the British law.

A general meeting of the medical profession held in Berlin, October 26, decided that after Jan. 1, 1914, the insured population of Germany, with the exception of Dresden, Hamburg and Berlin, should not receive any treatment from physicians through the insurance societies, unless these societies acceded to the demands of the physicians, or unless the government saw fit to intervene. The meeting was called by the president of the National Federation of Medical Societies, and was attended by 458 representatives of 384 medical societies, with a total membership of 21,207 physicians. The situation in Germany is a plain issue between the physicians on the tutes not only preparatory soil for the implantation of the disease, but also especially favorable culture-medium for its further propagation. One peculiarity is revealed by Robin's analysis of tuberculous lung tissue: While the blood and other tissues of the consumptive contain less than their normal contents of calcium, and the bones show evidence that lime has actually been withdrawn from them, the healthy parts of the lung adjoining the diseased portions show an increased amount of calcium, indicating, in Robin's opinion, that the calcium plays a defensive rôle in protecting the tissues against the infection.

On these data Robin founds a comprehensive plan of treatment of consumption and tuberculosis. Here it may be remarked that he uses these terms in a somewhat different sense from the usual one. Tuberculosis is, as it were, something added to the consumptive state. He transposes Niemeyer's celebrated dictum and says that "the greatest danger which threatens a consumptive is to become tuberculous." The indications for treating the disease are given under five headings: preventive medication, remineralization, direct antiseptic medication, local medication and antitoxic medication.

Robin uses tuberculin in doses just sufficient to provoke a focal but not a general reaction, hoping thereby to produce a stimulant or counterirritant effect on the focus or infection and the healthy surrounding tissues.

Space is lacking to criticize the fundamental assertions on which the theory of Robin is based. One may be permitted to ask, however, how the determination of the proportions of minerals in a tissue can prove a demineralization. May not this relative decrease in the amount of inorganic constituents reckoned on the weight of the fresh tissue be due in fact to an increase of contained water? Whether or not a similar criticism applies to his urinary determinations we are not able to ascertain from the figures in the book. Assuming the phenomena to be correctly determined, the question arises, May not this accelerated metabolism be due to a tuberculosis already existing? It is now pretty generally accepted that most persons acquire tuberculosis in infancy or early childhood; may not the symptoms observed in predisposed persons be really the slight but persistent action of an unhealed tuberculosis?

The Practitioner's Visiting-List, 1914. Leather. Price, $1.25. Philadelphia: Lea & Febiger.

The Physician's Visiting List for 1914. Sixty-Third Year of Its Publication. Leather. Price, $1 net. Philadelphia: P. Blakiston's Son & Co.

Medical Record Visiting List for 1914. Leather. Price, $1.25. New York: William Wood and Company.

The Physician's Visiting Lists offered by various publishers this year are, as usual, very attractive and useful. All of them contain special memorandum pages for each month ruled for each date, and amount and ledger page. In addition there are special pages for miscellaneous memoranda, obstetrical cases and practice, vaccinations, patients' and nurses' addresses and cash accounts. There are various calendars, tables, dosage lists, etc. All are well known, practical and attractive, and probably every physician has his particular choice.

The Doctor in Court. By Edwin Valentine Mitchell, LL.B. of the Massachusetts Bar. Cloth. Price, $1. Pp. 152. New York: Rebman Company, 1913.

This book contains a practical and interesting discussion of physicians' relations to the courts, and of the general principles of the laws affecting them. The first chapter is the most interesting and valuable to the physician who but seldom goes on the witness-stand. It contains advice that is well worth heeding, and the witness, if he follows it, would make a better spectacle than does the average doctor when giving evidence. The remaining chapters discuss the laws, including those on the regulation of the practice of medicine, which affect physicians and with which every physician should be familiar. While not large or exhaustive, this work is sufficiently complete for all ordinary purposes. The language is clear and non-technical. We commend the book to those who may be called into court, which means to all in the practice of medicine or surgery.

# Miscellany

## The Fundamental Basis of Nutrition

*From an Address by Dr. Graham Lusk before the New York Academy of Medicine*

It seems as though mankind has a right to a knowledge of the value of foods which a bountiful Nature has provided for human use. Even among educated persons there are the grossest errors of judgment regarding the nutritive value of a hen's egg, and few of those who eat at restaurants realize that the greater quota of the nourishment brought to them is not in the specific dish served but in the bread and butter which ostensibly is presented as a gift. The function of nutrition is to furnish fuel to the organism that the motions of life may continue, and furthermore, the workshops of life are in a constant state of partial breaking down and materials must be furnished to repair the worn-out parts. In the fuel factor and the repair factor lies the science of nutrition.

The heat given off by the body is found to be equal to the quantity of heat which would have arisen from the oxidation of just that quantity of protein, fat and carbohydrate estimated to have been destroyed. Drs. Du Bois and Warren Coleman discovered that a typhoid fever patient, during a period of five hours of rest in their calorimeter, produced the same number of calories as it was calculated that he should produce from the materials that were oxidized in his body. The contemplation of such a result drives home the fact that if the typhoid fever patient is to be kept from losing his own body-muscle and fat, he must be given the equivalent of 422 calories in food substance during a five-hour period. Measurement of the total heat production becomes a measure of the intensity of the life processes. All well-nourished mammals produce the same number of calories per square meter of surface. A normal man resting in bed in the morning, having been without food for fifteen hours, will manifest a minimum level of heat production. The basal heat production of an average man weighing 70 kg. will be 70 calories per hour, or 1,680 calories in twenty-four hours. If food were taken extra heat would be produced, but not exceeding 10 per cent. of the basal heat production, or 7 calories per hour, or 168 per day, so that the maintenance requirement of this man resting in bed was 1,848 calories daily. Beyond this the amount of fuel needed depended on the amount of work done. The normal man requires exercise and this calls for an additional amount of fuel. A man leading a sedentary life and taking perhaps two hours of exercise daily needs in round numbers 2,500 calories daily in order to provide proper nourishment and repair. Men doing heavy physical labor require at least 3,000 calories. A boy of 12 years requires 1,500 calories daily, and a baby when first born requires 100 calories. In fever hyperthyroidism and conditions in which the heat production of the body is far above the normal, increased nourishment is indicated. While the body may suffer from the deficiency of certain elements as calcium or iron, the really important material to be treasured and protected is the body protein. Proteins are especially valuable if they contain an array of units which when reunited in the body form body proteins. Proteins in which one or more of the necessary units are lacking can never be reconstructed into body proteins. Such inferior proteins occur among the plants. Plant proteins are reconstructed into beef proteins and thus beef proteins attain a higher biologic value than plant proteins. There can be no doubt, in view of the results of experiment, that meat, fish, milk and egg proteins possess superior value to the vegetable proteins. The proteins of rice and potato are of more value than those of bread, beans and Indian corn. Such facts make it possible to classify proteins into groups according to their physiologic value, and as milk is now sold in three grades, in like manner the protein of foodstuffs could be labeled A, B and C according to their physiologic value, and to Group D might belong gelatin and some other proteins that cannot replace body protein that is continually wearing away.

Protein is usually taken in excess of that bare requirement which is measured by the quantity necessary to repair the tissues. This excess is oxidized and used as fuel just as are fats and carbohydrates. Protein has one property out of all proportion to that possessed by the other foodstuffs in that it largely increases the heat production in the body. Persons maintained on a low-protein diet may suffer intensely from the cold. Glycocoll is one of the units that cause a marked increase in the heat production. In diabetes ingested glycocoll is completely converted into sugar without undergoing oxidation, and hence it acts as a chemical stimulus and not in virtue of its energy content. This heat-producing action is effected by all kinds of protein, by those of meat, fish, milk, egg, and such incomplete proteins as gelatin. In order to obtain the warming effect it is not necessary to purchase so costly an article as beef. Rubner believes that there should always be an excess of protein-constructive material in the diet so that if after physical exhaustion there is a depletion of the glycogen reserve there may be building units in reserve to quickly repair the tissue destroyed. It is not desirable for the laboring man to take the minimum amount of protein.

It has been known for a long time that life cannot be maintained on an absolutely pure mixture of salts, fats, carbohydrate and protein. The human organism is extremely sensitive to certain substances in minute quantities, as, for instance, epinephrin, the active constituent of the suprarenal glands, which is present in the blood in one part to 100,000,000 and is essential to human life. The relation of polished rice to beriberi has been recognized, and Funk has sought to isolate those substances, termed by Funk vitamins, which prevent beriberi and are necessary to the normal growth and nutrition of the animal tissue. If meat is eaten their direct ingestion from the plant becomes unnecessary. These vitamins enter into the composition of normal maternal milk; if a mother has beriberi these substances will be lacking in her milk and consequently the infant will also have the disease. Beriberi and scurvy do not exist in the United States, they only occur when a one-sided diet deficient in vitamins is depended on.

We may now consider the high cost of living in the light of scientific knowledge of food value. The efficiency of labor depends on its energy and constant repair, and it is certainly of no small account that the citizen should know how best to maintain the human machine at its maximum efficiency. The manufacturer of foodstuffs will not give this information; but if, through the medium of the schools and the press, every one knows that a man of sedentary habits requires 2,500 calories and a laboring man 3,000 calories and more, no one suffering from want will spend his money for a can of tomatoes which is little else than flavored water. It has been estimated that in a family of five comprising the father, a clerk, the mother, who does her own housework, two children, aged 9 and 6 years, and an infant 1 month of age, 7,750 calories are required daily. A study of the market values of staple foods in New York City, Jan. 28, 1913, showed that for an adult requiring 2,500 calories, or one-third as much as the entire family, the cost would not exceed 20 cents a day at the market price of fresh materials. When more than an average of 8 cents is expended for 1,000 calories of nutriment, the diet must include luxuries. The following market prices of various food staples shows the great variation in the price of 1,000 calories: glucose, 1⅔ cents; cornmeal, 2 cents; wheat flour, 2.5 cents; oatmeal, 2.8; canesugar, 3⅓; dried beans, 4; salt pork (fat), 4.5; rice, 5; wheat bread, 5⅓; oleomargarin, 7.5; potatoes, 7.5; butter, 10; milk, 10; smoked ham, 10.75; cheese, 11⅔; loin pork, 12.25; mutton (leg), 16.25; salt cod, 19.5; sirloin beef, 4; turkey, 40; fresh cod steak, 42. The relative amount of protein for the family of five is furnished by bread with the addition of 4/5 pounds of salt cod, or 3/5 pounds of smoked ham, or 4/5 pounds of cheese, or 2½ pounds of milk, or 1½ pounds of loin pork, or 1⅓ pounds of leg of mutton, or 1¼ pounds of cod steak, or 1⅓ pounds of sirloin steak, or 1⅓ pounds of turkey. It is evident that if each package of food were sold as containing so many calories, the widely heralded food value of such articles as Postum, for example, would "fold their tents like the Arabs, and as silently steal away." On the basis of these values it would cost a poor family from 50 to 70 cents a day for food; a family of moderate means where two servants are kept, from $1 to $1.40; and a wealthy family where six servants are kept, from $1.50 to $2.10. Whatever is spent above this is for waste or in the form of flavors of high price. Recently Miss Dorothy Lindsay made a report concerning the working classes in Glasgow in which she concludes that one of the main contributing factors of malnutrition among the poor is bad marketing. The experience of America in the matter of school lunches for the children of the poor shows that it is demonstrable economy on the part of the state to feed the undernourished child. But the state should also teach the mother the value of bread and milk, and that weak tea cannot take the place of milk in the nourishment of the child. In a study into the physiologic value of various food sold over the counter of Child's restaurants in this and other cities, F. C. Gephardt of the Russell Sage Institute of Pathology collected and analyzed 400 samples. For comparative standards bread and vintage champagne have been selected, neither of which was purchased in the restaurant.

FOOD VALUE OF PORTIONS, INCLUDING BREAD AND BUTTER WHEN SERVED IN CHILD'S RESTAURANTS

| | Cost, Cents | Calories, Total | Protein, Per Cent. | Calories for Five Cents | Cost in Cents per 1,000 Calories |
|---|---|---|---|---|---|
| Bread | 5 | 933 | 12 | 933 | 5 |
| Apple pie | 5 | 337 | 5 | 337 | 15 |
| Boston pork and beans | 15 | 828 | 12 | 276 | 18 |
| Ham sandwiches | 5 | 170 | 20 | 170 | 30 |
| Corned beef hash | 15 | 507 | 14 | 170 | 30 |
| Beef stew | 15 | 461 | 25 | 154 | 32 |
| Club sandwich | 25 | 409 | 20 | 52 | 61 |
| Sliced pineapple | 5 | 36 | 46 | 36 | 138 |
| Tomatoes, lettuce mayonnaise | 20 | 53 | 16 | 13 | 385 |
| Pint of champagne | 200 | 345 | 0 | 9 | 588 |

The extreme variability of the purchasing power of money for food stands here exposed in the lime-light. The government should take up this matter and give information regarding all foodstuffs sold in packages. The manufacturer could send his sample can to Washington to the Bureau of Chemistry, declaring that to be his standard and requesting information regarding his label. He should pay for this analysis as the patentee pays for his patent. If the government at any time finds the manufacturer of foods and "patent medicines" selling a material on the market of a different character from the standard deposited with the government, the manufacturer should be heavily fined. Manufacturers have complained that in other countries scientific men sit on the boards of directors of the manufacturers of foods and "patent medicines." In this country that sort of thing has been discountenanced and rightly so. The day of the sale of a man's scientific reputation and that of an institution with which he is connected has passed. The scientist has come to have sufficient altruism to believe that his services belong to all the people and not to a set of money-making individuals. Appeal is made to the understanding of physicians and of educated people of this country to take interest in this subject to the end that enlightened activity for the welfare of mankind may follow.

**Shipping Live Fish in the Frozen State.**—In the markets of Irkutsk, Siberia, fish are displayed for sale in the frozen state piled up like cordwood (see Nature's Cold-Storage Plant, quoted from *Am. Food Jour.*, The Journal, Oct. 19, 1912, p. 1429). Fish in cold storage are preserved frozen in slabs of ice. The latter method is now applied in the shipment of live fish. The method of shipping live fish in water is not feasible on account of the expense, as from 1 to 4 gallons of water are required for each pound of fish, according to the variety. Since the discovery by Pictet that fish may be frozen in blocks of ice without being killed, and that they will become as lively as ever after they are thawed out, a method has been devised for preparing them for shipment in ice. The method is described in the *Scientific American*. The fish in a large amount of water are placed in a closed tank, and oxygen under pressure is supplied. The greater portion of the water is then drawn off. The fish remain in good condition on account of the abundant supply of oxygen. The vessel containing the fish is then placed in a freezing tank and the fish are frozen into the ice formed. The blocks of ice containing the fish can then be piled up in the ordinary refrigerator car. On arrival at their destination the fish are put through a slow thawing process lasting ten hours, when they return to their normal state of active animation.

**Health as a Community Asset.**—To the extent that the inhabitants of a community are sick the community itself is diseased. The community has health only in so far as the people are free from disease. To a community health is a valuable asset. It insures prosperity. It attracts people. It increases the value of the land. Many letters are received daily at the Public Health Bureau at Washington from people who are contemplating buying land or moving from one state to another, asking about the health conditions of certain localities. They want to know whether there is much sickness in this or that locality, whether there is any malaria, much typhoid fever or tuberculosis, and whether there is a pure water-supply. People are thinking in these days of their physical welfare and have no desire to live in localities where insufficient attention is given to the prevention of disease and where there is more sickness than there should be. The community that has health has a distinct advantage in the competition for economic prosperity over the sick community.—John W. Trask, *Public Health Rep.*

## Medicolegal

### Charitable Associations Not Exempt from Liability for Failure to Guard Machinery

*(McInerny vs. St. Luke's Hospital Association of Duluth (Minn.), 141 N. W. R. 837)*

The Supreme Court of Minnesota, in affirming a judgment for the plaintiff, who was injured on a mangle while in the defendant's employ, holds that Section 1813 of the revised laws of that state of 1905, imposing on all persons and corporations owning or operating dangerous machinery the duty to cover or guard the dangerous parts thereof, so far as practicable, applies to charitable associations owning and operating such machinery, as well as to all other persons or corporations similarly situated. The duty thus imposed is absolute and not to be delegated, and a failure to discharge it renders the charitable association liable to its servants and employees who are injured in consequence of the neglect.

In reaching this conclusion, the court says that it is not to be understood as underestimating, or failing to appreciate to its fullest extent, the blessings bestowed on the destitute, and the poverty-burdened applicant for help. Its view is that the duty created by law for the protection of servants is absolute, and no employer should be exempt therefrom, except by action of the legislature. No public good can come from permitting one charitable corporation, by the failure of a duty imposed by law, to maim and disfigure its servants and employees, when, depending on the nature of the injury, their future welfare must of necessity be looked after by some other charitable association, public or private, or by already overburdened or poverty-stricken relatives and friends. No such situation should be brought about by an arbitrary rule of immunity from liability, applicable only to one class of persons, unless deemed by the legislature necessary to the existence and life of charitable associations.

Nor is the court to be understood as holding that the trust funds of the defendant may be applied to the payment of the verdict. That question was not involved. The defendant was not supported exclusively from such funds; on the contrary, its maintenance would seem from the evidence to come principally from patients who pay for services rendered them.

### Physician's Right to Claim Safe Exempt

*(Sterman vs. Hann (Ia.), 141 N. W. R. 934)*

The Supreme Court of Iowa reverses a judgment against the plaintiff, a physician, who, it says, sought by an action in replevin to recover a half interest in a safe levied on by the defendant, as constable, under an execution, and claimed by the plaintiff to be exempt under the Iowa law, on the grounds that he was a physician and surgeon and used it in and about his business. He owned the safe in common with his wife, each owning an undivided half interest. It was, however, in his possession, and under his control, with the knowledge or consent of his wife, and he used it in and about his business for the purpose of keeping therein his professional instruments, books and accounts, and certain rare and valuable medicines. The defendant constable made no claim, under the execution, against the interest of the wife. Therefore, as against the constable, the plaintiff had the right to the possession of his wife's interest in the property, and if his interest in the property was exempt, as the court holds it was, he had the right to hold that, too, as against the levy of attachment. He, therefore, had dominion over the entire property. He had a right to take, use it, and keep it, and this right came to him from the other party having a joint interest with him in the property. He had dominion over the property, with the consent of his wife, and had a right to use it in connection with his business, and for the purposes for which it could, and would, be used were he the sole owner. The safe was exempt, in the hands of the plaintiffs, the same as office furniture and the supplies of a lawyer are exempt. In other words, a physician can hold, as exempt, a safe kept and used by him in his office in connection with his business as physician and surgeon, for the purpose of keeping therein his professional instruments, books and accounts, and medicines. It must be borne in mind that exemption laws are to be liberally construed; that they are given to the debtor to secure to him the necessary comforts of life for himself and family, and are enacted on the ground of public policy, for the purpose of saving debtors and their families from want, by reason of misfortune or improvidence, and should be so construed as to carry out the intent and purpose of the legislature.

### Validity of Ordinance Prohibiting the Maintenance of "Museums of Anatomy"

*(City of Chicago vs. Shaynin (Ill.), 101 N. E. R. 224)*

The Supreme Court of Illinois holds constitutional an ordinance of the city of Chicago which provides: "It shall be unlawful for any person, firm or corporation to own, conduct or operate any exhibition commonly known as a museum of anatomy, or other exhibition, show or place of amusement which is open to the general public, whether admission thereto is restricted by sex and age or not, or whether a fee for admission thereto is charged or not, wherein the principal part of the exhibition is illustrative of the human anatomy, or wherein are exhibited any books, pamphlets, circulars, pictures, charts, diagrams, models, casts or other articles, paintings, drawings or designs of any kind illustrating or describing the genital organs, or containing any other obscene, lewd, indecent or immoral exhibition of any kind, when such museum or other exhibition is conducted for gain or profit, either directly or indirectly, or for the purpose of advertising or in connection with a place where medical treatment is offered or medicine is sold, or for any immoral purpose whatever."

The court says that if it be argued that the cure of the sexual diseases portrayed by these models is not an unworthy object, it may be answered that the exhibition of offensive and repulsive models on sexual subjects, which may pander to the morbid tastes and arouse the sexual desires of those who are attracted to the place, does not have any necessary relamust be attributed to something which distinguishes butter from the ordinary fats, for not only do lard and olive oil lack this growth-promoting power, but young rats grow on "protein-free milk" foods when all of the lard is replaced by carbohydrate and no ether-soluble substances are present in the food.

It thus appears improbable that glycerids of the fatty acids ordinarily present in foods are responsible for the promotion of the growth observed when butter-fat replaces lard in the diet of rats which have ceased to grow. Lecithin and other phosphorus or nitrogen-containing substances are excluded by the absence of phosphorus and nitrogen from butter-fat; and cholesterol by the fact that even more of this substance has been obtained from lard than from butter. So far as Osborne and Mendel's experience has shown, the addition of butter-fat to our natural "protein-free milk" foods gives them an efficiency quite comparable with that of milk-food in promoting recovery and the completion of growth.

The exact chemical differences between the adequate butter-fat and the inadequate lard (which determine success and failure, respectively, in the food-mixtures employed) are far from being satisfactorily known. Chemical examination of the butter-fat indicates that the effective component is not a phosphatid or any inorganic substance, inasmuch as nitrogen, phosphorus and ash are lacking in the product employed. It is suggestive to note that in the case of the lard we are dealing essentially with a fat-mixture deposited in storage depots of the animal organism; in the other, the butter-fat represents the product of metabolic activity and synthesis on the part of the cells of the mammary gland. What, if anything, this distinction between cellular product and reserve fat may mean physiologically, remains to be investigated. Butter-fat has shown a further interesting nutritive superiority over lard. At certain periods of the year, particularly in summer months, the authors have frequently failed to secure satisfactory growth on the dietaries which proved adequate during the usual period of sixty to one hundred days at other seasons. Occasionally young rats in the stock colony have exhibited a similar "epidemic" of poor growth at the same season. The failures are, however, not common to rats fed on the milk-food; and Osborne and Mendel have lately observed that the seasonal failure is also averted by the addition of butter-fat to the usual "protein-free milk" food-mixtures. Again, another type of nutritive deficiency exemplified in a form of infectious eye disease prevalent in animals inappropriately fed is speedily alleviated by the introduction of butter-fat into the experimental rations. On the other hand, no amount of butter-fat will induce growth on certain dietaries in which the proportions and nature of the inorganic salts are inappropriate or the quantity and character of the protein is inadequate. Egg yolk-fat appears to behave like butter-fat; some other oils have thus far proved no more efficient than lard. Such considerations make it evident that the comparative value of the natural fats employed in nutrition must be determined, as well as the individual rôle of the different proteins, carbohydrates and mineral nutrients.

17. **Intraperitoneal Lysis of Tubercle Bacilli.**—Manwaring and Bronfenbrenner found that tubercle bacilli injected into the peritoneal cavities of tuberculous guinea-pigs, rats, rabbits, dogs and monkeys rapidly disappear from the peritoneal fluids, while persisting in the peritoneal fluids of normal control animals. This disappearance they regard as being in part due to an adhesion of the injected bacilli to the peritoneal leukocytes and a fixation of the leukocytes on the omentum. The injected tubercle bacilli can be recovered quantitatively from the peritoneal cavities of normal guinea-pigs from one and one-half to two hours after the injection, while from tuberculous guinea-pigs only 65 per cent. of the bacilli can be recovered at this time. Isolated peritoneal tissues from tuberculous guinea-pigs have the power of destroying tubercle bacilli *in vitro.* A second factor reducing the number of tubercle bacilli free in the peritoneal fluid is therefore an actual lysis of the bacilli. The intraperitoneal lysis is not due solely to substances present in the circulating fluids, since the phenomenon cannot be produced by these fluids *in vitro,* and since a lytic power cannot be passively conferred even by a direct transfusion of blood from tuberculous to normal animals. The intraperitoneal lysis is apparently due to specific changes in the fixed peritoneal cells of the tuberculous animals.

18. **Tetany.**—It has been the author's aim to determine in what particular the blood is altered during tetany so that it can produce hyperexcitability of the motor nerves. As a working hypothesis it has been assumed that (1) there may be a lack of calcium in the blood and tissues; (2) there may be a circulating poison which like an oxalate could render inactive the circulating calcium, and (3) there may be a substance in circulation vaguely resembling strychnin in its action on the nervous system and directly causing the hyperexcitability. The authors do not attempt to decide which, if any, of these explanations is the true one, but certain experimental results are brought forward. If tetany blood be used to perfuse a normal leg the excitability of the nerves rises to a characteristically high level and the addition of parathyroid extract to the blood has little or no effect in lowering this excitability. Parathyroid extract whether from the ox or the dog fails when injected into the circulation of an animal in tetany to reduce the excitability of the nerves markedly or permanently, although it seems to affect the more sensitive ganglion cells, thus cutting off excessive impulses to the periphery. Although the nerves remain hyperexcitable, tetany is usually much diminished or abolished entirely.

This seems to be analogous to the action of ether or any other anesthetic which may inhibit the activities of the ganglion cells, although it leaves the nerves excitable and able to conduct impulses. An animal in tetany relaxes instantly on being given ether although the excitability of the nerves to electric currents is little changed. Bleeding followed by the replacement of the blood with an indifferent solution free from calcium stops tetany and lowers the excitability of the nerves. Probably this cannot be ascribed to the removal of a circulating poison, but rather to a general disturbance of the nutrition of the nervous system. Oxalate-like substances introduced into the circulation rapidly, and for a short time only, may kill the animal, but they seem to produce no change in the excitability of the nerves. If the solution is injected very slowly and over a long period the protective action of the body seems to be overcome and the excitability of the nerves rises to high levels. This seems to resemble somewhat the latent period after the destruction of the parathyroid before tetany begins. Direct analysis of the blood shows that as compared with the normal, the blood of an animal in tetany is very poor in calcium. Administration of parathyroid extract does not increase this calcium content. On the contrary, if the extirpation of the parathyroids has been incomplete so that tetany does not appear, the calcium content of the blood is that of the normal animal. Even yet, therefore, in spite of efforts to shake it, the theory that tetany is closely dependent on a disturbance of the calcium content of the blood is supported by stronger evidence than any other idea, but much remains to be done before a clear conception of the process is reached.

19. **Chicken Tumor Due to Filterable Cause.**—A spontaneous chicken sarcoma, peculiarly fissured by blood sinuses and with

a tendency to intracanalicular extension into them, has been transplanted by Rous and Lange and studied in eight successive groups of fowls. Histologically the growth is a characteristic neoplasm, while in its transfer to new hosts a real transplantation is obviously involved. The development of the first few series of transplantation tumors was very slow. They exhibited the histologic structure of the original growth and had the same tendency to metastasize to the skeletal muscles. Recently the tumor has grown more rapidly and in a higher percentage of hosts. With this has come a simplification of structure to that of a pure, spindle-celled sarcoma. Fowls of an alien variety (Plymouth Rock) form quite as good hosts for the tumor as those of the sort (Brown Leghorn) in which it was originally found. It has grown in pigeons, rats or mice. The question of the cause of tumor is not taken up. It has been found to be due to an agent which will pass through Berkefeld filters. The growth is quite distinct in its characters from the other two transplantable neoplasms of the fowl (a spindle-celled sarcoma, an osteochondrosarcoma) which have such a cause. No growth like it has been observed among the forty-three spontaneous tumors of the fowl that have come under the authors' observation.

21. **Production of Experimental Nephritis.**—The repeated injection of small doses of horse serum and egg-white in dogs, cats, rabbits and guinea-pigs that have been sensitized to these proteins, has been found by Longcope to cause injury to the cells of various organs and tissues with resulting inflammatory reactions. The changes are especially marked after intraperitoneal injections in the peritoneum and after intravenous injections in the livers of rabbits and cats, and in the myocardium and kidneys of all groups of animals. In dogs and rabbits, especially, there develops a well marked nephritis characterized by degeneration and necrosis of the epithelium of the loops of Henle, of the collecting tubules, and less frequently of the convoluted tubules. This is accompanied by an extensive small round-cell infiltration of the interstitial tissue and later the formation of connective tissue. Together with these changes there are acute and chronic alterations in the glomeruli of all groups of animals. Egg-white in large doses is itself injurious to the kidney of animals, but this slight primary toxicity is probably greatly enhanced through previous sensitization of the animal.

2. **Lipoid Anaphylaxis.**—Attempts were made by Wilson to sensitize guinea-pigs to lipoids of varying chemical and biochemical properties extracted from rabbits' livers. The results were negative. Lipoids extracted from egg-yolk in a similar manner, and which differed considerably from the liver lipoids, also failed to produce anaphylaxis. Some doubtful evidence was obtained that a pure lipoid from one source might sensitize an animal to a lipoid of different origin. Dried liver substance and dried egg-yolk do not sensitize to lipoids derived from these substances. Lipoids from yolk of egg sensitize animals to dried liver substance, but liver lipoids will not sensitize to dried egg-yolk. Pure lipoids from any substance will sensitize an animal to a crude extract of the substance, but repeated injections of pure lipoids do not produce anaphylaxis.

3. **Cytology of Condensed Milks.**—Unsweetened liquid preserved milks have no bacteriology, for, Andrewes says, if they were not sterile they would not keep. The case is very different with sweetened condensed milks. In the examination, by culture, of forty-five samples, forty-three of which were machine-skimmed products, Andrewes found living bacteria in every one. Even a good and popular brand of condensed milk yielded a moderate number of colonies of *Staphylococcus albus*, but of the tins examined, forty-three were cheap machine-skimmed milks. Thirty one samples yielded almost pure cultures of staphylococci, among which *Staphylococcus pyogenes aureus* was conspicuous and often predominant. These samples were almost all from a single foreign country, emanating in tins bearing the labels of three different brands, from one single factory. Andrewes' opinion is that the presence of *Staphylococcus pyogenes aureus* in large numbers in a condensed milk is objectionable and should probably constitute a ground for condemnation, even though the potential harmfulness of such a product is unproven. Efficient pasteurization, before condensation and before the addition of sugar, should prevent the presence of such organisms in the final product, however difficult it may be to destroy them afterward, for in the majority of condensed milks they are absent or but scantily present.

14. **Arterial Lesions in Rheumatic Fever.**—Klotz urges that greater attention be given to the various types of acute aneurysms and their relations to acute rheumatic fever; and further, that the almost constant presence of some inflammatory reaction in the ascending limb of the aorta be recognized as an associated condition in this disease.

16. **Hepatic Insufficiency.**—The estimation of any one element of the nitrogen partition of the urine, Macadam believes, is useless as a guide to hepatic efficiency; their interrelationships have to be considered. After the injection of hydrazin sulphate there is an increased excretion of total nitrogen, as found also in phosphorus poisoning. It is probably due to the disturbance of glycogenic function with the subsequent direct or indirect disintegration of the muscle protein. The increase in amino-acid nitrogen, both absolutely and relatively to the total nitrogen, is the most constant feature of the urinary nitrogen partition during the hepatic disturbance produced by hydrazin. Further, this increase is invariably the earliest abnormality to be detected. After hydrazin injection the urea percentage of the total nitrogen increases, and the ammonia diminishes, slightly in sublethal, markedly in lethal, experiments. Neither acetone nor diacetic acid was detected in the urine during the course of any of the experiments. The excretion of creatinin is found to be practically constant, while there is a large excretion of creatin, which appears to be dependent on impaired glycogenic function exerting its influence on the muscle metabolism, rather than on liver inefficiency, leading to a decrease in the conversion of creatin to creatinin. This seems to be indicated by the increased catabolism of "muscle flesh" as calculated from the output of total creatinin.

19 *Intestinal Disturbances Consecutive to Gastro-Enterostomy. A. Mathieu and R. Savignac.

17. **Hemorrhagic Infarct of the Pancreas.**—Chabrol presents evidence to show that infection by way of the blood or from the intestines is always a factor in splenophlebitis with hematemesis, infarct of the intestine from mesenteric thrombosis, and infarct of the pancreas from thrombophlebitis.

19. **Intestinal Disturbances from Abnormally Rapid Evacuation of the Stomach.**—Mathieu and Savignac review eleven cases in which more or less serious bowel trouble followed a gastro-enterostomy; the stomach content was passed along through the new outlet before there had been time for the gastric juice to act on it properly. In some cases there was intermittent or continuous diarrhea, sometimes extremely rebellious; in others there were discomfort and pain after meals, resembling the syndrome with gastroptosis. Roentgenoscopy will exclude a fistula between the stomach and the colon, incomplete stenosis of the small intestine and ulcer in the jejunum, which the symptoms suggest. The surgeon should aim to make the gastro-enterostomy continent so that it will retain the stomach content for the normal period. When this has not been accomplished, the patient should restrict his diet to bland foods leaving little waste, and the meals should be small. The soft diet should be supplemented by some preparation of opium, and by hydrochloric acid and gastric juice. Reclining during the period of discomfort, and wearing a girdle to help support the sagging organs are also useful when the intestine becomes distended and heavy and drags on the abdominal plexuses.

23 Nodose Erythema with Tubercle Bacilli in the Blood-Stream. L. Landouzy.
24 Hernia plus Mesenteric Cyst. P. Lecène.

21. **Pathogenesis of Gall-Stones.**—Chauffard comments on recent research by Grigaut, published in his thesis last summer under the title the "Cycle of Cholesterinemia." The work was done in Chauffard's laboratory and apparently demonstrates that when there is deficiency in the production of bile salts, the cholesterin is not held properly in solution and hence it is retained in the serum. The excess of cholesterin in the blood causes part to drop out at points favoring sedimentation, especially in the gall-bladder. The primal trouble is thus an insufficiency on the part of the liver. Whatever the cause of this liver disturbance, whether it is due to over-eating, too sedentary life, obesity, pregnancy or inherited taint, treatment should aim to restore normal functioning or supplement by administration of bile salts the lacking elements in the bile.

30 *Diathermia in Leprosy. P. Unna.
31 *Intussusception in Infants. (Ueber die sogen. Invaginatio ileocoecalis.) F. Lotsch.
32 Importance for Psychiatry of Jodl's System of Psychology. H. Marcuse.

25. **The Red Bone Marrow in the Femur.**—Hedinger has examined over a thousand cadavers to determine the distribution of the red marrow in the bones, especially in the femur, and has recorded data in five hundred, including forty-four cases of sudden death from suicide or accident. His findings conflict with the statements in the text-books.

26. **Alimentary Fat in the Myocardium.**—Wegelin found fat in the heart muscle in a previously robust insane young man who died in an accident, and also in an infant cadaver. The fat in the myocardium in these cases must be accepted as a physiologic phenomenon. This assumption is corroborated by the findings in his extensive research on white rats and other animals. They all confirm the fact that when fat is taken in the diet there are liable to be deposits in the myocardium without signs of degeneration.

29. **Diabetic Coma.**—Blum discusses the three forms of coma, the cardiovascular, the form with dyspnea and the form in which the dyspnea type merges into the cardiovascular type. The blood-pressure is not always subnormal at first. In regard to the ocular tension, he says that the loss of water is not sufficient alone to explain the reduction; the salts must be involved also. Under treatment with large doses of alkali the ocular tension is liable to return to normal. This reduction in ocular tension may occur outside of coma, as in a recent case of acute fatal gastro-intestinal disease. The ocular tension was 4 or 5 mm. fourteen hours before death, but there was no tendency to coma. The loss of water in the profuse diarrhea was undoubtedly responsible for the change in the ocular tension.

Blum's experience has been that stimulants and epinephrin are unable to arrest the progressive weakness of the circulation in coma. This shows that they do not influence the cause of the vascular trouble. Improvement follows only when the acid becomes neutralized by sufficient intake of an alkali. He gives sodium bicarbonate or citrate, 5 or 10 gm. by the mouth, every half hour until the urine gives an alkaline reaction. The alkali is taken in carbonated water or wine or in capsules which pass through the stomach unmodified. In case of a tendency to diarrhea, he adds equal parts calcium carbonate to the sodium bicarbonate or citrate, up to a total of 250 gm. of the mixture in twenty-four hours. He has never witnessed any benefit from the alkali given by the rectum. Untoward by-effects are liable to follow intravenous infusion of the alkali unless it is given in the form of solutions of the sesquicarbonate, obtained by boiling sodium bicarbonate. The concentration should not go above that corresponding to a 6 per cent. solution of sodium bicarbonate. The infusion should not be repeated unless profuse diuresis guarantees that part of the sodium salt has been eliminated. By heeding these factors, intravenous infusion is practicable. He does not think it advisable to keep up the alkali indefinitely, on account of injury to the stomach. When coma is once installed, a purge is of little use, but great improvement is liable to follow a purge in the precoma stage.

30. **Diathermia in the Nervous Form of Leprosy.**—Unna has applied in seven cases this method for inducing high temperatures in the depths of the tissues, and states that it has a remarkable effect in arresting the pains at once. With continued applications permanent results can be attained, deep infiltrations being absorbed. It also loosens up the tissues, rendering them more amenable to general measures.

31. **Intussusception in Infants.**—Lotsch reports the recovery of two infants out of twelve operated on for ileocecal invagination. In only five cases was the interval less than twelve hours before the operation and the two children who recovered were in this group. In six additional cases of invagination the trouble was in the small intestine and the children were

older; this group includes also three adults. Attempts at manual reduction and reduction by high injections have little prospect of success. No time should be wasted on them, he insists, as the only chance for recovery is in an early operation.

### Medizinische Klinik, Berlin

*November 16, IX, No. 46, pp. 1879-1920*

33 Chemotherapy of Tuberculosis. C. Bruck.
34 *Diagnosis and Treatment of Hematuria. E. Portner.
35 The Food of the Japanese. K. Suto.
36 *Operative Treatment of Detachment of Retina. (Netzhautablösung.) Elschnig.
37 Combined Tincture of Iodin and Ichthyol Treatment of Furunculosis. F. Berger.

41 Physical Measures in Treatment of Skin Diseases. E. Saalfeld.
42 Etiology of Molluscum Contagiosum. B. Lipschütz.
43 Technic for the Wassermann Test. (Zur Frage des verfeinerten Wassermann mit bes. Berücksichtigung der sogen. Paradoxen Sera.) F. Graetz. Commenced in No. 45.

34. **Hematuria.**—Portner insists that the cystoscope is indispensable in examining a case of hematuria, and there should be no delay in applying it. The only exceptions are with acute gonorrheal cystitis and hypertrophy of the prostate. He discusses the interpretation of the cystoscope findings, warning that both kidneys may be involved, and also that the discoloration of the urine may be due to hemoglobinuria. To exclude chronic nephritis, the urine should be examined after exercise and during bed-rest. If no cause for the hematuria can be discovered, the bleeding and painful kidney should be opened up in six or eight weeks at latest, as the trouble may be a tumor. Bleeding from instrumental injury generally stops of itself but infection should be warded off with hexamethylenamin and copious drinking. If there is much hemorrhage, a retention catheter may help to arrest it. Slight bleeding from the posterior urethra generally occurs with a few drops of pure blood at the end of micturition; gonorrhea and tuberculosis of the bladder may show hematuria of this kind. With profuse hemorrhage in the posterior urethra the blood runs into the bladder and mixes with the urine. Blood in the sperma is usually a sign of gonorrheal inflammation of the seminal vesicles, but it may be an early sign of a tuberculous process or of cancer of the prostate. If the prostate is found enlarged in a case of hematuria without pain, the prostate is generally responsible for it, and if the hemorrhage recurs repeatedly, malignant disease may be assumed unless the cystoscope reveals some cause in the bladder. The hemorrhage with calculi in bladder or kidney is harmless unless infection is superposed, but the slightest suspicion of cancer requires operative treatment. It is a comparatively recent discovery that hemorrhage may occur with chronic nephritis alone. The operation undertaken to remove the assumed calculus or tumor cured the tendency to hemorrhage and taught that nephrectomy is the only means to remove danger from this source. Hematuria with an incipient tuberculous process in the kidney is like hemoptysis in early pulmonary tuberculosis, important and useful as it permits treatment in time to be effectual.

36. **Operative Treatment of Detachment of the Retina.**—Elschnig states that he has punctured and injected 1 c.c. of the patient's own serum or salt solution in twenty cases; on both eyes in two of them. By aspirating out part of the fluid that has accumulated beneath the retina and, practically simultaneously through another cannula, injecting fluid in front of the retina to push it back into its normal place, approximately normal conditions can be restored. Seven of the eyes were much improved but the condition was aggravated in ten. In one case a mycotic process developed, finally destroying both eyes. He has never had a complete cure, being less fortunate in this than Birch-Hirschfeld. But the method may arrest the trouble and save partial vision at least, when under less vigorous measures the eye is inevitably doomed.

38. **Pathologic Importance of the Tonsils.**—Röder declares that if the physician is not content with a cursory inspection of the apparently intact tonsils, but insists on lifting the anterior palatine arch and examining all the recesses, and squeezes the tonsils, drawn out by a suction apparatus, he will become convinced that the lymphatic vessels at the entrance to the throat take a leading part in the functioning of the organism as a whole. Not only joint troubles but a number of other local and general disturbances improve after a housecleaning of the tonsils. This not only clears away disease-breeding detritus, etc., but it starts up a healthy circulation of lymph through the parts. Fresh lymph pours into the tonsils, and the data presented testify that a strong current of lymph setting into the tonsils is an important element for health. When this current becomes obstructed by detritus, etc., we have trouble at once. In one case of incipient measles he applied the suction apparatus to the apparently sound tonsils and aspirated considerable pus; in a few minutes the swelling of the face and eyes began to go down. Cleansing out the tonsils may cure a persisting bad odor of the breath. Under normal conditions the act of swallowing squeezes out the secretions and detritus in the tonsils; the bad odor is thus most evident fasting.

This conception of the important part played by the tonsils necessarily forbids routine tonsillectomy. Treatment must aim to cure the tendency to chronic inflammation and restore the functioning of the tonsils. He applies the tonsil suction apparatus with moist cotton in the spoon blades. Local applications of tincture of iodin, etc., are irritating and do no good. The general circulation of the lymph is stimulated with brine baths, inunctions and internal administration of cod liver oil, and iodin or 1 per thousand mercuric cyanid by the drop, every hour or two. He has never found it necessary to resort to the knife, although this might be indicated if the tonsil had hardened so that the plugs of pus could not be forced out. Röthlisberger's massage sometimes proves useful, especially when the effect is enhanced by pressure from without on the massaging finger. In conclusion Röder reiterates that by this means the physician's own knowledge and skill relieve the patient of his pains and disease without the necessity for drugs or for an operating specialist or chemicals.

39. **Sudden Death in Bathing.**—Güttich describes the serious symptoms which follow irritation of the vestibular apparatus with cold water poured into an ear with perforated drum. Not only nystagmus but vertigo, vomiting and general collapse have been observed. Even with a sound membrane, these symptoms may develop if water at a temperature of 10 C. is used for the test. These facts amply explain many cases of sudden death in bathing. The water penetrates through the perforation, or the force of the water in diving, or a wave dashing against the ear may burst a weakened tympanic membrane. Passow has related cases of this kind. There may be a temperature irritation in the internal ear just from the coldness of the water alone, acting on the exterior of the body. The consequent irresistible vomiting or collapse under the water might easily cause death. A meal not long before renders the vomiting reflex easier to elicit. The reaction as a whole is liable to be proportional to the difference of temperature between the water and the air. Persons with perforated membrane should be warned against diving and bathing in too cold water; they should plug the ear with oiled cotton. The ears of a drowned person should be examined for perforation of the membrane.

### Münchener medizinische Wochenschrift

*November 18, LX, No. 46, pp. 2553-2600*

44 *Esophageal* Cardiogram. (Registrierung des Druckes im rechten Vorhof und Wert des oesophagealen Kardiogramms für die Erklärung des Jugularvenenpulses.) A. Weber.
45 Experimental *Production* of Concrements. (Experimentell erzeugte Ablagerungen von Cholesterinestern und Anhäufungen von Xanthomazellen im subkutanen Bindegewebe des Kaninchens.) N. Anitschkow.
46 *Desiccated Antitoxin and Serums. (V[illegible] lyaxiegefahr durch eine neue Art de[illegible] Injektionsfertiges Trockenserum.) [illegible]
47 *Obliterating Arthritis. E. Veiel.
48 Practical Identity of Radium and Roentgen Rays. A. Pagenstecher.

49 *Epinephrin in Recurring Osteomalacia. H. v. Salis.
50 *Tonic Neck Reflexes in Man. R. Magnus and A. de Kleijn.
51 Rumination in Three Generations. (Ausserordentlicher Fall von menschlichem Wiederkauen.) v. Gulat-Wellenburg.
52 *Lymphoblast and Myeloblast Leukemia. G. Herxheimer. Commenced in No. 45.
53 *The High School for Physicians and Patients. XI. M. Nassauer.

46. **Desiccated Antitoxin and Serums.**—Eichholz states that experimental research has apparently demonstrated that a suspension of desiccated serum in olive oil seems to retain all the therapeutic possibilities unimpaired while the serum is absorbed so much more slowly and gradually that there does not seem to be any danger of anaphylaxis or serum sickness. The desiccated serum naturally cannot be used where speedy action is wanted, but it may be found useful in prophylaxis and in cases in which there are reasons for anticipating trouble from anaphylaxis.

47. **Obliterating Arteritis.**—Veiel reports two new cases similar to those published by Erb in which young men developed intermittent claudication after a crushing injury or long chilling or inflammation causing obliterating inflammation in the artery of the foot or leg. In one of his cases the claudication disturbances came on spasmodically even when the patient was at rest. There is nothing to suggest arteriosclerosis in either case, but the nervous system in all such cases seems to have been predisposed by abuse of tobacco.

49. **Epinephrin Treatment of Recurring Osteomalacia.**—Salis calls attention to the remarkable efficacy of a course of epinephrin, according to Bossi's principles and technic, in the case of a woman of 42 who had had osteomalacia develop during her various pregnancies and recur during the intervals, a martyrdom through sixteen years. None of the usual measures, including castration eleven years before, had given more than transient relief, but under the epinephrin she lost her pains and inability to walk and there was no further local tenderness, so that she is now clinically cured.

50. **Neck Reflexes.**—Magnus and de Kleijn have continued their study of the peculiar tonic reflexes in the limbs to be elicited by turning the head of decerebrized laboratory animals. The same reflexes can be elicited in patients with disease shutting off the brain, and they here report the case of a girl of 9, a total idiot, with no apparent perception of sound or light, blind, deaf and dumb. By turning the child's head over to the right side, the right arm and leg at once straighten out while the left arm and leg become flexed. Turning the head to the left, the left arm and leg stretch out straight while the right arm and leg become flexed. Drawing the child's head over so that the right ear is brought nearer to the shoulder, the right arm and leg relax, while the left arm and leg straighten out; the reverse occurs when the left ear is drawn down to the left shoulder. Lifting and lowering the head do not elicit any appreciable reflexes. The reflexes elicited are permanent, that is, the limbs stay in the position they assume in the reflex movement.

52. **Leukemia Simulating Typhoid Lesions.**—Herxheimer emphasizes that the leukocytes in leukemia are below par to such an extent that they are not able to defend against infections, and hence the leukemic are particularly subject to infectious processes. The gums, the throat, the nose, have often been the seat of infectious processes, and thirty-eight cases are on record in which the infectious processes were located in the intestines, the findings suggesting typhoid or paratyphoid ulceration. This was particularly evident in Herxheimer's three cases of myeloblast leukemia. One of the cases had been labeled typhoid until the blood-count disproved this. The intestinal findings were exactly those of typhoid, but all the tests for typhoid or paratyphoid bacilli proved negative. The ulcerations were in the ileum exclusively and they were evidently the work of the colon bacillus alone. In conclusion he reports a case of lymphatic leukemia on which became superposed a myeloblast leukemia. The mediastinal tumor, tumefaction of the pancreas and enlargement of the heart were evidently the work of the latter. The patient was a youth of 16 with chronic leukemia; he died from suffocation from the rapidly growing tumor in the mediastinum.

53. **The High School for Physicians and Patients.**—Here Nassauer draws the picture of the lady who goes heavily veiled to the physician's office and complains of heart trouble requiring a thorough examination. It reveals nothing abnormal except possibly a little accelerated heart-beat. A few days later the physician is summoned by telephone early and told to come to her home at 11. He waits till nearly 2, and then apologizes profusely for having been detained. He finds the husband there then and the maids returned from various errands on which they had been sent away in the morning.

Another sketch shows the vagaries of the memory when it comes to paying the physician; the apparent inability of patients to realize or keep count of the number of times they call the physician to their homes; their surprise when they find that it mounts up to such a number of calls when they thought it was only three or four during the whole year at most; the way in which a patient will keep on paying the same small sum which the physician asked years ago, the first time this patient consulted him, when the patient was in almost indigent circumstances. Now that fortune has smiled on her she never thinks of increasing the office fee, and yet, this very patient, in the anteroom is liable to expatiate on the physician's high charges and perhaps drive away some one waiting to consult him but not able to pay the high fees he understands from the woman's remarks are the custom at this office. Nassauer also sketches the richly dressed woman, an old client, and a "very grateful one," as he has saved her life, she realizes, on more than one occasion. At that time she had been an impecunious wage-earner but later married her employer and was now wealthy. Although she often called at his office she never thought of paying him for his services. By keeping up her modest payments to the company in which she had taken out health insurance while employed, she had his services gratis.

58 *Vaccination against Chicken-Pox. (Om skyddsympning mot varicellæ.) C. A. Kling.

57. **Hypophysis Extract in Obstetric Practice.**—Gårdlund concludes from his experience with hypophysis extracts that they may prove useful oxytocics but they cannot always be relied on as the effect seems to depend on the individual response of the uterine musculature. This varies in a wide range. In the extremely susceptible actual tetany of the uterus may be induced.

58. **Vaccination against Varicella.**—This article is the same as the one reviewed in abstract 36, p. 2277, here accompanied by colored plates showing the positive findings on the arm after vaccination.

### Ugeskrift for Læger, Copenhagen

*November 6, LXXV, No. 45, pp. 1777-1814*

59 *Radiotherapy in Gynecology. A. Maag.
60 Appendix as Sole Content of Femoral Hernia; Two Cases. I. U. Gerdes.

59. **Radiotherapy in Gynecology.**—Maag reviews a number of articles on this subject and compares the outcome of treatment in over a thousand cases, tabulating further the views of the different authors in regard to indications and contra-indications. His conclusions are in favor of refraining from operative treatment of uterine myoma as Roentgen treatment can cause the myoma to retrogress and the patient does not require hospital care and the treatment is painless. The data presented seem to show also that Roentgen treatment is the sovereign measure for all purely climacteric disturbances.

# JOURNALS INDEXED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT
## JULY-DECEMBER, 1913

---

The following journals have been indexed in the Current Literature Department of THE JOURNAL during the past six months. Any of the foreign journals, except those starred, will be lent by THE JOURNAL to subscribers and members in the United States for a period not exceeding three days. Requests for periodicals should be addressed to the Library of the American Medical Association and six cents in stamps should be enclosed. This covers the average expense of mailing a journal. Domestic journals can be obtained by sending the approximate amount direct to the respective publishers. Thus most of the journals indexed are accessible to the general practitioner, no matter where he may be located.

† These journals are not indexed in the Current Medical Literature Department of THE JOURNAL, but may be borrowed under the usual conditions.

# EXPLANATION OF THE USE OF THE INDEX

This is an index not only to the reading matter in The Journal, but also to original articles in the principal medical periodicals of this and other countries. The reading matter appearing in The Journal is distinguished by the use of black-faced numerals.

The letters used to explain in which department the matter indexed appears are as follows: "E," Editorial; "C," Correspondence; "T," Therapeutics; "Ml," Medicolegal; "P," Propaganda for Reform; "ME," Medical Economics; "ab," abstract; the star (*) indicates an "Original Article" in The Journal.

This is a subject index and one should, therefore, look for the chief word, with the following exceptions: "Deaths" and "Society Proceedings" are indexed under these titles at the end of the letters "D" and "S." Matter pertaining to the Association is indexed under "American Medical Association."

All matter is indexed under the most important word of the heading used in The Journal, and also under the subject heading. For instance, abscess of the brain will be found under "abscess," as well as under "brain." Such titles as "ocular manifestations, etc." have been indexed under "Eye." Cross references have been liberally used.

The figures in parentheses refer to the paragraph, the number following to the page in The Journal.

ABSCESS, temporosphenoidal, with meningeal symptoms, ***1209**

This reference is to an original article in The Journal, as shown both by the star and by the black-faced numerals indicating the page.

AARON and Rosenbach signs for appendicitis, **2001**

This reference, as indicated by the black-faced figures, is also in The Journal, and on turning to page 2001 we find an answer to a question in the Department of Queries and Minor Notes.

ABSCESS, liver, emetine in (5) **1936**

In this reference, the (5) indicates that the article is in the Current Literature Department and the fact that the page number is in black-faced type shows that the article is abstracted and discussed in The Journal. Turning to page 1936, we find (5) refers to an article by R. L. Spittel in the *British Medical Journal*, October 25.

ABBOTT'S method of treating scoliosis, (104) 513

The fact that in this last reference the page is given in ordinary type indicates that only the title of the article is given. Turning to page 513 we find that the numeral (104) refers to a paper on that subject by S. Kleinberg which appeared in *Surgery, Gynecology and Obstetrics*, July.

In the Author's Index are the names of the authors of articles which have appeared in The Journal of the American Medical Association and of articles that have been listed from week to week in the Department of Current Medical Literature as having appeared in other journals. The black-faced numerals indicate that the article is in The Journal, either in full or in abstract. The star (*) preceding the page number, indicates an original article.

---

# SUBJECT INDEX

AARON and Rosenbach signs for appendicitis, **2001**
ABBOTT'S method of treating scoliosis, (113) 154, (106) 224, (104) 513, (111) 899, (62) 1493, (112) 1496
  method in correction of fixed types of scoliosis complicated by visceral derangements, especially those of cardiac variety, (8) 1569
ABDERHALDEN, comments of, on communications of Folin and Denis, (69) 897
  protective ferments, specificity of, (89) **1853**
  refuses to come to Vienna, **210**
  serodiagnosis applied to gastro-intestinal tract, (136) 1757
  serodiagnosis, articles on, 2039
  serodiagnosis, cancer, (80) 814, (116) 1003, **1461**—E, (47) **2195**
  serodiagnosis, cancer, sodium flourid in, **1736**
  serodiagnosis, epileptics, (128) 2024
  serodiagnosis in internal medicine, importance of, (110) **2199**
  serodiagnosis, infectious diseases, (78-80) **814**
  serodiagnosis, neurology, **1826** (92) **2111**
  serodiagnosis, pregnancy, (92) 366, ***484**, (47) **518**, (75) 519, (93) 630, 788, (80) 814, (130) 996, (116) 1003, (128) **1005**, (56) 1411, (4) **1485**, (12) 1847, (75) 1853, **1921**, (77) 1939, (119) 1942, (105) 2022, (145) 2114, (91) 2281
  serodiagnosis, pregnancy, technic, (14) 1068
  serodiagnosis, present status of, 493—E, 2269—ab
  serodiagnosis, psychiatry, (85) **1940**, (121) **2199**
  serodiagnosis, scarlet fever, (73) 2286
  serodiagnosis, thymus tissue, (90) 1580
  serodiagnosis, thyroid disease, (142) **1758**
  serodiagnosis, tuberculosis, (98) 2111, (34) **2277**
ABDOMEN, acute, (4) 2274
  acute, abdominal cutaneous reflexes in diagnosis of, (59) 2273
  acute, conditions which mimic, (53) 1849
  acute, diagnosis, (13) 996, (84) 2274
  acute, on board ship, (61) 1331
  adhesions, ***1952**
  air in, after laparotomy, (71) **717**
  anoci-association with special reference to operations on, (138) 368
ABDOMEN, aorta, clamping inferior vena cava and, below diaphragm, carbon dioxid and oxygen content of blood after, (41) 1747
  appendix free in, without suppurative peritonitis, (59) 808
  cancer, diagnosis of, possible errors in plea for exploratory laparotomy, (93) 1664
  cases, unusual, (45) 307
  complications following laparotomies, ***2045**
  contusion, (71) 1493
  diagnosis of vesical complications in appendicitis and other lesions of, (4) 431
  differential diagnosis of diseases of upper, (79) *144*
  drainage in surgery of pelvis and, (106) **2104**
  drainage, question of, (73) 144
  enlargement, chronic, in children, with special reference to new differential sign between rachitis and tuberculous peritonitis, (73) 994
  ether for rinsing out, in perforative peritonitis, advantages of, (126) **1082**
  gas in open, vast accumulation of, (138) 1669
  gunshot wounds of, (81) 307, (40) 517, (57) 715
  incision and intestine anastomosis in cancer of colon, (21) 226
  incision in ovary cysts, (124) 2104
  incision, technic, (146) 317
  incision, transverse, in gynecology, (27) 2276
  inflammation in children, acute, diagnosis and treatment, (19) 1575
  inflammation, pneumonia simulating, (11) **996**
  lumbo-ilio-sacral support and its uses, advantages and limitations, (40) 897
  malaria simulating acute surgical disease of, (16) 142
  measurements in pregnancy, value of, ***746**
  mimicry of diseases of upper, by omentum adhesions, **1483**—ab
  muscles, congenital defect of, with anomaly of urinary apparatus, (18) **1073**
  muscles, stretched, in parturients, electricity for, (129) 2024
  pain, (94) 223
  pain, acute, and vaccination, (10) 1329
  pain, acute, in pregnancy, (23) 1490
  pain and tenderness, points of, (1) 991
ABDOMEN, perils, acute, (2) 712
  Ptosis of: See Splanchnoptosis
  respiratory movement, absence of, as indication of pericarditis, (37) 438
  roentgen-ray work, ***2217**
  roentgenoscopy of diseases of thorax and, (74) 1488, (115) 1574
  roentgenoscopy of obscure conditions in, in infants and children, ***1422**
  sponge left in, liability for, 2094—Ml
  Surgery: See also Laparotomies
  surgical diseases of, in children, (53) 438
  tetany with disease of, bad sign, (153) **2025**
  tissues, sensitiveness of visceral organs and, in general, (122) 719
  tumors, differentiation of, (171) 1758
  wound, closure of, after celiotomy, (54) 365
ABDUCENS nerve, paralysis of, and acute mastoiditis, (25) 1324
ABORTION, as diagnostic agent for infectious abortion in cattle, value of, (33) 2190
ABORTION, (83, 86) 366
  artificial, considered from standpoint of eugenics, (97) 69
  contagious, bacillus of, in cow's milk, **1379**—E
  contagious, in cattle, phenol reported to be specific for, 927—E
  criminal, attempted, in absence of pregnancy, (76) **1414**
  criminal attempted, in absence of pregnancy, medicolegal bearing, (104) 375
  criminal, attempted, with extra-uterine pregnancy, rupture of tube, (153) 377, (59) 2108
  declining birth-rate and (153) 1758
  early, (30) **1409**
  epinephrin and, (134) **2113**
  febrile, (91) **815**, (127) 909
  hemorrhage after labor and, (72) 813
  in Vienna hospitals, treatment, (134) 232
  infectious, of mares and jennets in Kentucky, etiology of, investigations of, (39) 511
  jaundice following, (69) **1753**
  laparotomy for removal of fallopian tubes and, (135) **1335**
  malpractice and, (82) 1754
ABORTION, missed, and missed labor, (95) 1846
  operative treatment, (158) 233
  spontaneous, abnormal, causing cervico-vaginal fistula, (78) 1853
  streptococcus, conservative treatment, results, (68) **519**
  treatment, (70) **717**, (126) 720
  tubal or uterine, hemorrhage from, differential diagnosis, (127) **155**
ABSCESS: See also Cellulitis; Felon; Phlegmon
ABSCESS, brain, frontal lobe, originating in ear, (15) 1323, (33) 2107
  brain, metastatic, (44) **627**
  brain, traumatic, (44) **1410**
  cerebral, (33) 1575
  cold, phenol and camphor in joint disease and, (160) **73**
  due to streptothrix eppingeris resembling staphylococcus infection, (13) 809
  fixation, infections treated by, (41) 1848
  fixation, mushroom poisoning treated by, **1388**
  kidneys, multiple, congenital and prostatic urethra stricture, *244
  liver, (29) **625**
  liver, emetine in, (5) **1936**
  liver, non-amebic, and gastro-intestinal myiasis, ***1457**
  liver, unusual cases, (7) 1664
  lung, artificial pneumothorax in, (43) 1944
  lung, case study, (97) 1664
  lung, during typhoid, operative cure, (170) 74
  lung, not due to tuberculosis or bronchiectasia, operative treatment, (66) **1412**
  mediastinum, tuberculous, (14) **997**
  orbit, and eye neuritis complicating dacryocystitis, (74) 1845
  paranephritic, differential diagnosis, (147) 1083
  peritonsillar, general sepsis following, (117) 1327
  peritonsillar, phlegmon starting as, and extending downward as far as second ring of trachea, (62) 994
  retropharyngeal, (68) 512, (115) 1327
  retropharyngeal, in adult, (85) 1664
  scarlatinal, conservative treatment, (95) **815**
  sinus, complicating acute middle-ear suppuration, (43) 902
  spine, (12) 1487
  subdiaphragmatic, (30) 1069
  subphrenic, (79) **905**

- ABSCESS, subphrenic, after appendectomy, (115) 816
  - subphrenic, gaseous, diagnosis of, (186) 1338
  - subphrenic, perforated common bile duct followed by, operation and recovery, (8) 515
  - temporal, subperiosteal, originating in ear without intra-osseous suppuration, (60) 1934
  - temporosphenoidal, originating in ear, operation, recovery, (23) 1324
  - temporosphenoidal, with meningeal symptoms, *1209
  - thyroid, with pure cultures of typhoid bacilli 21 years after typhoid and followed by acute exophthalmic goiter, (61) 519
- ABSORBINE, Jr., 1552—P
- ABSORPTION, fat, test for, simple, (73) 1000

  pernicious, with myeloblastosis, (111) 1668
  pyrodin, destruction of blood in, course of, (87) 2281
  resistance of nerve cells to, a proof of hardness of nerve cells in intestine, 2244—E
  resisting powers of red blood-corpuscles in jaundice and, (168) 233
  serotherapy of, with serum taken after venesection, (166) 233
  significance of, as operative risk, (100) 1489
  splenectomy for splenomegaly with severe, (84) 1078
  splenic, etiology and surgical treatment, (28) 2102
  splenic, in children, (68) 67
  splenic, recovery, (61) 1493
  treatment, (50) 1331
  varying types of, four cases, (29) 1662
ANENCEPHALY, (133) 1418
ANESTHESIA, (95) 898, 1656—ab, (55) 1849
  alkaloids administered before, *834
  anoci-association and, (94) 307, (64) 366
  *chloroform or ether? (173) 74*
  chloroform, shock during, scopolamin, morphin and atropin in preventing, (26) 2194
  ciliary ganglion enucleation of eye under, (117) 224
  cocain, hernia with radical operation under, (136) 224
  ether, (96) 2282
  ether, bronchitis after, and oxidation products of ether, (156) 157
  ether, heated, for general, (80) 623, (79) 1332, (137) 1418
  ether, in nose and throat operations, (32) 1491
  ether percentages, *830
  ethyl chlorid and gas, *leukocyte* count in, (14) 713
  ethyl chlorid general, (48) 311
  ethyl chlorid in dentistry, (115) 909
  finger elevation of hyoid bone in general, Chevalier Jackson method of, (36) 2101
  for course of laparotomy, importance of, (229) 1672
  general, and allied phenomena, nature of, (122) 1669
  general, differential pressure maintained through nose for, (150) 2201
  general, lesions of cornea after, (145) 721
  general, rupture of ovary cyst, spontaneous, during, two cases, (47) 1577
  general, under atmospheric over-pressure, (97) 718
  general, with internal disease, (64) 1412
  in acute inflammations of mouth and pharynx, (21) 1408
  induction of operative, and relief of earache by infiltration of auriculotemporal and tympanic nerves, (24) 1487
  insufflation, Meltzer's, intubation with, technic for, (41) 2277
  intratracheal insufflation, (30) 364, *839
  intratracheal insufflation, ether, (38) 65, (13) 225, (121) 513
ANESTHESIA, intratracheal, practical application of, (133) 1847
  labor and, (70) 813
  local, (15) 436, *842
  local, and nerve blocking in major and minor surgery, comparative value of, (131) 1490
  local, in abdominal surgery, 1322—ab
  local, in operations for hernia, (6) 2101
  local, in radical cure of inguinal hernia, (99) 809
  local, of brachial plexus, paralysis of phrenic nerve after, (122) 522
  local, technic for, (171) 1338
  local, tonsillectomy under, operation, new, results, *1227
  nerve-blocking as substitute for *general, in surgical operations,* *1040
  nitrous oxid and oxygen, (93) 307, *838, (49) 902, (119) 1749, (93) 2274
  *oil-ether, (82) 2274*
  oxygen, lack of, and, 1050—E
  pantopon and scopolamin general, experience with, (71) 2196
  recent work on, (49) 2018
  *rectal, (170) 147*
  rectum etherization, (93) 2021
  review of about 650, (79) 623
  *sacral, in surgery, (108) 2022*
  shock with various methods of, (85) 2110
  spinal, (7) 510
  spinal, by tropacocain, (5) 225
  spinal, combined with brief ethyl-chlorid administration, (23) 1830
  spinal, dangers and disadvantages of, ((96) 1935
  spinal, general, (41) 1937
  spinal, in gynecology, obstetrics and abdominal surgery, *1358
  spinal, in military service, 600 cases, (17) 809
  *surgical,* lacrimal gland in, (6) 225
  view of, 968—E
ANESTHETIC and other vapors and gases, anesthetometer for measuring *and mixing, (153) 1328*
  combining morphin with hypnotics and, danger in, (120) 1082
  *cousin entitled as physician to recover for administering,* 890—Ml
  *effect of different ones on pathology* of kidney in acute uranium nephritis, (59) 1070
  general, methods of administration of, (123) 1936
  influence of kidney lesions in determining selection of surgical risks and, 1399—ab
  influence on mouse tumors, (221) 1672
  liability for negligence in administration of, 1655—Ml
  lumbar intraspinal injection of, in *gastric crises of tabes dorsalis,* (118) 375
  pharmacologic research on, (115) 1756
  potassium permanganate as local, to genito-urinary mucous membranes, *196, (134) 1072
  uniform vapor of, safe and con*venient method of giving, (132)* 1847
  various, and methods, *1516
ANESTHETIST and surgeon, relations that should exist between, (78) 623
ANESTHETOMETER for measuring and mixing anesthetic and other vapors and gases, (153) 1328
ANEURISMORRHAPY, (13) 364
ANEURYSM abdominal aorta, rupture of, into stomach through ulcer, (125) 816
  aorta, performation of, into superior vena cava, eighteenth case, (56) 1851
  aorta rupturing into vena cava, *1810
  arteries of small caliber, (99) 1668
  arteriovenous, of axillary blood-vessels of thirty years' duration, (28) 2018
  arteriovenous, of superficial femoral blood-vessels, *2155
  ascending aorta of mycotic-embolic-thrombotic origin, (203) 1672
  cerebral arteries, (120) 720
  cervical rib simulating, (15) 1068
  *formation of, pathology of syphilitic aortitis* with contribution to, (47) 222
  innominate artery (101) 2282
  internal iliac artery, (20) 708
  posterior tibial artery, rupture of sac, operation by Matas method, *(49) 365*
ANEURYSM, suture of blood-vessel with, (90) 718
  thoracic, blood-pressure in, (15) 1665
  thoracic, roentgenoscopy of, (90) 223, (22) 1936
  traumatic, military experiences of, (48) 1331
ANGINA, Ludwig's: See Ludwig's angina
  Vincent's: Vincent's Angina
ANGINA pectoris, (8) 64, (79) 712
  *pectoris,* continuous attacks of, *1642
  pectoris, ill-effects of excretion in, (3) 303
  pectoris, reflex or protective phen*omena of, (103) 1935*
  pectoris, subintrant, (40) 1937
  phlegmonous, and diphtheria, differentiation of, (158) 1084
  treatment of pains, *193
  *Vincent's: See Vincent's Angina*
ANGIOKERATOMA, four cases, (191) 1672
ANGIOMA, carbonic acid snow in obliterating, (107) 308
  *infective, of Hutchinson, (32) 2190*
  serpignosum, (57) 1663, (32) 2190
ANHIDROSIS and diabetes insipidus, (129) 909
ANHYDROUS oily substances, auto*clave in sterilization of, value* of, (39) 2195
ANILIN dye in shoes or stockings, poisoning from, (58) 999
  in surgery, 302-ab
ANIMALS, *aleukocytic, exudates in,* (80) 717
  and plant growth, Roentgen rays simulating, (137) 1757
  blood relationship of, as displayed *in composition of serum proteins,* (54) 62
  *can they utilize nitrates? 204—C*
  cold-blooded, metabolism studies on, (16) 2321
  dead, power of boards of health to regulate removal of, 2267—Ml
  domestic, and epidemic poliomyelitis, (133) 1497
  fossil, pathologic findings in, (85) 1494
  heat, source of, 2305—E
  parasites of, invading human *beings, (135) 1856*
  pathology in plants and, comcomparative, (64) 716
ANIRIDIA, bilateral, complete, ectopia lentis, pathologic cupping of *discs, (127) 1072*
ANKLE clonus without gross disease of central nervous system, (5) 304
  fracture, immobilization of, technic for, (141) 317
  fracture, various types of, (188) 160
  paralyzed, arthrodesis for, ultimate outcome, (56) 716
ANKYLOSIS, hip arthroplasty, (60) 512
  hip, Murphy's arthroplastic method for, (77) 2020
  jaw, due to cicatricial *formations* in cheek, palate mucous membrane flaps in, *245
  knee, vicious, operative treatment, (58) 1938
  *petrolatum injections in arthritis* and in prevention of, (135) 818
ANKYLOSTOMA infection in Udi district of central province, Southern Nigeria, (26) 437
ANKYLOSTOMIASIS: See Uncinariasis
ANOCI-ASSOCIATION and anesthesia, (94) 307, (64) 366
  based on clinical experience of *3,000 cases,* (122) 1327
  in laparotomy, reducing mortality, *newer methods of, *1501*
  in laparotomy, value of, (57) 2273
  kinetic theory of shock and its prevention through, (35) 370
  value of, (49) 1331
  with reference to laparotomies and goiter operations, (111) 224, (138) 368
ANOPHELES and malaria, (3) 1401
  Malayan, revised list of, (30) 1665
  species of, that transmit human *malaria, (3) 363*
ANSTIE'S limit in alcoholism, 704
ANTARCTIC, Mawson's expedition to, (8) 899
ANTHRACOSIS, (169) 1499
ANTHRAX *serum, successful,* (183) 1672
  treatment, (43) 711
ANTI-ALCOHOL and narcotoic advocates meet, 2168
ANTIBODY *content of* rabbit serums, changes in, (137) 909

ANTIBODY derived from without, (82) 1332
  development of, in serum of patients recovering from acute lobar pneumonia, (41) 1571
  ferments, protecting, (56) 2278
  for human blood-corpuscles produced in monkeys, (34) 2190
  formation of, not affected by artificial feeding, (107) 2111
  in serum during first stage of syphilis, (189) 1338
ANTI-DISEASE society organized, 1728
ANTIETAM, bloodiest day in American history, (104) 63
ANTIGEN, bacillus abortus as, in complement fixation reaction of blood in children and infants, (3) 1931
  bacterial, disappearance from blood of, (161) 378
  comparative study of, for Wassermann reaction, *754
  corpus luteum, serodiagnosis by, (18) 305
  Deycke-Much, tuberculosis treated by, (84) 1853
  in Wassermann reaction, (64) 2196
  in Wassermann reaction, cholesterin added to alcoholic extracts of tissues used for, (62) 222
  in Wassermann reaction, liver of tuberculous guinea-pigs and cattle as, (118) 1081
  technic for obtaining, (116) 154
ANTIGONOCOCCUS serum, 869, 2242
ANTIKENATOXIN, Weichardts', 1059, 1476
ANTIMENINGOCOCCUS serum, 869
  serum in acute gonorrheal epididymitis, (51) 1077
ANTIPEPSIN in blood prevents autodigestion of tissues, (118) 719
ANTIPNEUMOCOCCUS serum, 869
ANTIPYRIN, influence of phagocytosis, (37) 2190
  paradoxical action of, in partially and completely decerebrate rabbits, (46) 2192
ANTISEPTIC, potassio - mercuric iodid as an, (86) 1071
  urinary, (3, 4) 1406
ANTISTREPTOCOCCUS serum, *661, 869, 2242
ANTITOXIN content and curative action of diphtheria antitoxin, (76) 228
  desiccated, and serums, (46) 2326
  diphtheria, (87) 435
  diphtheria, as immunizing agent, 885
  diphtheria, content of human blood-serum, (116) 2023
  diphtheria, intravenous administration of, (28) 992, (150) 1336
  diphtheria, necessity for educating public in value of, (106) 1334
  tetanus, 568
  tetanus, administration and value of, 687—E
ANTIVACCINATIONISTS, campaign against, 502
  irrepressible, 1437—ab
  physicians, conviction of, 290
ANTIVIVISECTION activity, recent, 282—E
  Congress, Washington, 2244—E
ANTROPOIDS, proposed establishment of breeding place for, 495—E
ANTRUM knife, new, (19) 1487
  maxillary, air embolus following exploratory puncture of, (7) 142
  maxillary, closing sinus between mouth and, method of, *1613
  maxillary, something about, (85) 63
ANUS, artificial, permanent, (96) 1755
  fistula, operation and after-treatment, (33) 437
  malformations of rectum and, (81) 153
  pruritus, operation for, (100) 145
  pruritus, peritinax, (93) 2016
  psychology of, (36) 1330
ANUSOL suppositories, 1392—P
AORTA, abdominal and thoracic, partial occlusion of, by bands of fresh aorta and of fascia lata, (11) 708
  abdominal, aneurysm of, rupture of, into stomach through ulcer, (125) 816
  abdominal, clamping inferior vena cava and, below diaphragm, carbon dioxid and oxygen content of blood after, (41) 1747
  abdominal, segment of carotid artery substituted for segment of, (93) 68
AORTA, aneurysm of ascending, of mycotic-embolic thrombotic origin, (203) 1672
  aneurysm, perforation of, into superior vena cava, eighteenth case, (56) 1851
  aneurysm rupturing into pulmonary artery, (48) 221
  aneurysm rupturing into vena cava, *1810
  changes, pathologic, of horse not analogous to human arteriosclerosis, (100) 815
  rupture of, spontaneous, (66) 1852
  stab-wound of, (230) 1672
  syphilis of heart and, diagnosis and treatment, (87) 1489
  syphilitic changes in, of monkey, (155) 318
  syphilitic, pathology of, with contribution to formation of aneurysms, (47) 222
  syphilitic, radial pulse in, difference in, (40) 714
  syphilitic, roentgenoscopy of, (94) 2110
  syphilitic, sclerosis of, (112) 314
  syphilitic, with symptoms of insufficiency of left ventricle, (54) 1077
  thoracic, aneurysm of, roentgenoscopy of, (22) 1936
  thoracic, reducing caliber of, by plication or infolding of its walls, practicability of, (27) 1069
APHTHOUS fever, transmission from animal to man, history of, (63) 66
APLASIA, forebrain, type of cerebral maldevelopment, (55) 1751
  motor, and deafness following epilepsy, (146) 1005
  motor, as only indirect consequence of trauma of skull, (113) 440
  sensory, (108) 308
  surgical, (66) 512
APOMORPHIN, contaminating morphin, alleged, 496—E
  hydrochlorid in vomiting of pregnancy and in nausea generally, 1628—ab
APONAL, new hypnotic, (32) 310
APOPLEXY: See Brain, Hemorrhage
APPARATUS: See also Instrument
APPARATUS, air, superheated, improvised, (138) 1757
  Allis ether inhaler, improvement in, suggested, (108) 367
  anesthetometer, for measuring and mixing anesthetic and other vapors and gases, (153) 1328
  bed-frame, adjustable, *490
  blood-count, (130) 1334
  blood-letting, (106) 2016
  chain-saw and automatic trephine with accessory instruments, electrically propelled, (40) 2014
  colostomy, new, (97) 2016
  comparison microscopes, *1958
  cross-cylinder holders, two, new, (83) 513
  device, mechanical, for blood-vessel anastomosis, (94) 1934
  drain-pan for operating table, new style, *197
  ear speculum, illuminated, *491
  electric hand lamps, simple attachments for, (114) 2 4
  electro-cardiophone, for controlling heart and heart-sound tracing, (22) 142
  energometer, Christen's, measurement of energy of pulse with, (47) 1851
  extension of limb in operative treatment of fractures, (26) 1330
  fixation, made of absoluble animal bone, *333
  for aseptic means to introduce hand into uterus, (111) 816
  for determining percentage of ether vapor obtained by passing air over liquid ether, *830
  for freezing-point determination, new form of, (5) 991
  for general anesthesia in surgery of children, *847
  for inhalation of chloroform, (57) 999
  for perfusion of isolated organs especially isolated mammalian heart, (55) 1748
  for proctoclysis, new, (103) 2104
  irrigation basin, new, (121) 2017
  olfactometer, (128) 1757
  orthopedic, duralumin a new alloy for, (27) 2271
  perineorrhaphy retractor, (98) 2016
  pneumothorax, (184) 1338
  radium, stolen, 879
APPARATUS, respirator, an appliance for resuscitation by producing enforced respiration, (66) 808
  salvarsan and neosalvarsan, apparatus for administration of, *867
  Schaefer, resonators with special reference to, (92) 63
  sounding-board as aid in diagnosis of diseases of thorax, (44) 622
  stomach-tube, collapsible-weighted, and new gastric glass bulb, (47) 1488
  syringe, precision, for accurate injection of small quantities, new, holders for such syringes and for other purposes, (41) 511
APPENDECTOMY, care after, (90) 1002
  in infant born with whole intestine outside of abdomen, *199
  subphrenic abscess after, (115) 816
  308 cases, (70) 2196
APPENDICITIS, (126) 367, (88) 1489, (143) 1847, (88) 2016
  Aaron signs for, 2001
  about cecum and terminal ileum, chronic, roentgenoscopy of, both congenital and acquired, (109) 1846
  acute, (27) 1487
  acute, operation for, primary closure of abdominal wound, (28) 1330
  bile tract infections and, 2009—ab
  calculus in right ureter simulating, 1929—ab
  cancer of pelvic colon and ovary tumor necessitating repeated abdominal section, (4) 1490
  cases simulating, (5) 899
  catarrhal, is there such a condition? (56) 434
  chronic, (96) 1002, (54) 1849
  chronic, causing limping and mistaken for right hip-joint disease, (53) 1938
  chronic, cecum mobile and pericolic membrane, (83) 1406
  chronic, in relation to hyperacidity of gastric juice, (66) 435, (67) 512
  chronic, ninety-eight consecutive operations for, (22) 1487
  chronic, referred pain over stomach or heart on steady pressure of McBurney's point as sign of, (61) 372
  chronic, roentgenoscopy of, (38) 1571
  chronic, ulcer of stomach and duodenum, and gall-bladder disease, differential diagnosis between, (111) 1749
  chronic, vs. duodenal ulcer and their association, (12) 142
  chronic, with no acute phase, (123) 1855
  combination of conditions producing, *2240
  contracture of psoas parvus muscle simulating, (17) 1746
  diagnosis, mistakes in, (47) 627
  diagnosis of chronic, by pinching appendix, (15) 805
  diverticulitis and, (69) 1332, (35) 1577
  electricity in, (104) 1668
  endothelioma of Meckel's diverticulum simulating, (31) 1575
  experimental research on, (141) 156
  hernia, femoral, and, (180) 2026
  ileus and, (81) 814
  in children, (65) 152, (16) 1329
  in infants, (49) 311, (80) 1573
  in young women, (20) 2101
  ligation of ileocolic vein with mesenteric pyemia after, advantages of, (79) 2196
  liver with, (254) 1674
  malaria simulating, (16) 142
  mucous colitis and membranous pericolitis, co-relation of, (63) 366
  nephrolithiasis and differential diagnosis, (41) 364
  operation early, (258) 1674
  operation, 601 cases, (97) 154
  pain in stomach with, (69) 1852
  peritonitis, general, due to, and complicating pregnancy, (9) 1847
  pregnancy complicated by, (1) 1485
  pregnancy complicated by, high mortality of, (119) 1757
  pseudomyxoma of peritoneum originating from, (32) 1409
  retrocecal, and rare anatomic anomalies, (54) 1468
  Rosenbach signs for, 2001
APPENDICITIS, round worms caused symptoms leading to diagnosis of, (3) 623
  suppuration after, tardy, (72) 1939
  tapeworm and, (173) 1671
  treatment and pathology, (72) 711
  tuberculosis and, (79) 153, (122) 1757
  vesical complications in, and other lesions of abdomen, diagnosis, (4) 431
APPENDIX, black, four cases, (19) 516
  cancer, primary, etiology and histogenesis of, (95) 1940
  chronic disease of gall-bladder and, as etiologic factors in production of digestive symptoms, (43) 364
  cysts, pseudomyxomatous, in, (86) 905
  diseases of, (68) 808
  exclusion of, (173) 1338
  free in abdomen without suppurative peritonitis, (59) 808
  hernia of, ileo-appendicular, (141) 1327
  in hernia, (176) 74, (60) 2326
  in intra-uterine pregnancy, decidual reaction in, *1702
  meningitis due to escape of threadworms into peritoneal cavity through perforated, (2) 514
  palpation findings at, (170) 2202
  pinching, in diagnosis of chronic appendicitis, (15) 805
  removal versus exclusion of, (162) 446
  roentgenography of ileocecal valve and, 1841—ab
  roentgenoscopy in differential diagnosis, (112) 1574
  stomach ulcer and, 949—ab

ARSENIC therapy in anemias, theory of, 1048—E
*ARSONVALIZATION in* benign and malignant tumors of urinary bladder through operating cystoscope, value of, (136) 2104
ARTERY, *affections of, painful,* stretching or resecting perivascular nerves in, (82) 2020
  aneurysm of internal iliac, (20) 708
  *aneurysms of small caliber,* (99) 1668
  arm, loss of pulsation in, due to puncture wound over right clavicle, (22) 1848
  brachial, direct suture following rupture, result of traumatism, (23) 1746
  brachial, pulse flow in, (5) 431
  calcified, rigidity of, (3) 1847
  carotid, segment of, substituted for segment of abdominal aorta, (93) 68
  cerebellar, inferior, posterior, occlusion of, *179
  cerebellar, thrombosis of, (159) 318
  cerebral, aneurysm of, (120) 720
  coronary, embolism of anterior, fatal, (33) 714
  coronary, isolated, action of nitrites and drugs of digitalis group on, (58) 1748
  femoral, embolus in, operation for, successful, (133) 232
  histologic study of, improved method, (29) 64
  hypogastric, ligation of, in abdominal hysterectomy for cancer, (56) 999, (122) 1497
  iliac, circulation disturbances in ligation of, to avoid, (83) 2197
  innominate, aneurysm of, (101) 2282
  lesions and acute articular rheumatism, (14) 2323
  *ligation of, with lymphatic block,* in advanced cancer of pelvic organs, (3) 1842
  mesenteric, embolism and thrombosis of superior, (13) 1746
  mesenteric, thrombosis of, (73) 307
  ovarian and internal iliac, ligation of, for inoperable cancer of uterus combined with curettage and cautery, (16) 624
  phrenic, hemorrhage from isolated tear in, (80) 629
  pulmonary, obstruction of, due to cancer, (31) 1848
  pulmonary, sclerosis of, secondary to certain chronic lung conditions, (45) 811
  pulmonary, sclerosis of, unilateral, (33) 1324
  pulmonary, surgery, (12) 709
  pulmonary, *thrombosis in right* heart and, antemortem, as cause of death in lobar pneumonia, (21) 1330
  renal, accessory, right intermittent hydronephrosis due to two, and cured by their removal, (179) 378
  spasm, (49) 438
  surgery, 800—ab
  testing permeability of, in gangrene, (53) 1666
  thyroid, *exophthalmic* goiter cured by ligating one superior, (42) 1488
  tibial, posterior, aneurysm of, rupture of sac, *operation by* Matas method, (49) 365
  uterine, atheroma of, hemorrhages into angiomatous fibromyoma of uterus and, (25) 997
ARTERIORRHAPHY, (143) 146
ARTERIOSCLEROSIS, (70) 144, (107) 712, (10) 996, (64) 1579
  and high tension, treatment, (12) 309
  before 30, (88) 630
  calcium in origin of atheroma and, treatment by abstention *from* calcium in diet, (160) 1499
  diagnosis, early, (83) 63, (73) 2274
  etiology of, (123) 1335, (45) 1571
  experimental, (251) 1674
  pathologic changes in aorta of horse not analogous to human, (100) 815
  symptoms and physical signs, (130) 1574
  treatment, (100) 809
  uterus, and uterine hemorrhage, (73) 68
ARTERIOVENOUS anastomosis for impending gangrene, (14) 363, (120) 1417, (47) 1751
ARTERIOVENOUS aneurysm of axillary blood-vessels of thirty years' duration, (28) 2018
  aneurysm of superficial femoral blood-vessels, *2155
ARTHIGON in gonococcus infection, *intravenous injection of, reaction* to, (111) 2198
ARTHRITIDES, surgery of, 2010—ab
ARTHRITIS See also Gout; Joint Diseases; Rheumatism
ARTHRITIS, 700
  chronic, *670
  chronic, focal infection as causative factor in, *819
  chronic, pathology of, (44) 1405
  deformans and otosclerosis, analogy between, (12) 1490
  deformans, clinical *aspects and* medical management of, 2003—ab
  deformans, experimental, (144) 1669
  deformans, genito urinary surgery of, and allied varieties of chronic rheumatism, (63) 1663
  deformans, greatly improved by physical means, 141—ab
  deformans, present conception of, 1485—ab, 1563—ab
  hip, monarticular, rheumatoid, *surgical treatment,* (62) 1488
  infectious, (46) 1492
  meningococcus, serotherapy of, (47) 144
  *obliterating,* (47) 2325
  pathogenesis, 779—E
  petrolatum injections in prevention of ankylosis and in, (135) 813
  rheumatoid cause of, primary, (18) 2275
  rheumatoid, differentiation of, (13) 1664
  rheumatoid, gout and rheumatism, (6) 712
  rheumatoid, hypophysis extract or dx in, (31) 1488
  rheumatoid, metabolism, prevention and successful treatment of, (14) 2270
  rheumatoid, vasomotor phenomena as premonitory symptoms in, (12) 996
  streptococcus, 2007—ab
  streptococcus, chronic, *724
  streptococcus, experimental, in monkeys, (68) 2016
  suppurative, experimental, (77) 1754
  uric acid in roentgenoscopy of (123) 720
ARTHRODESIS for paralyzed ankle, ultimate outcome, (56) 716
ARTHROPLASTY, (141) 2106
  hip ankylosis of, (60) 512
ARTISTS and physicians, (118) 2111
  data requested on famous anatomists and great, 703—C
ASBESTOS, *action on* certain physiologic substances, (12) 2274
  action on radium and thorium in solutions of their salts, (7) 2274
  minerals and allied materials action of, on bacteria, (6) 2274
ASCARIS, ileus and volvulus from presence of, in children, (150) 318
  *invagination* of intestine or lipoma in adults from, (98) 229
  pregnancy and, (32) 2194
ASCITES, (42) 711
  chronic, (118) 2104
  differential diagnosis in, (71) 144
  due to failing compensation in heart regurgitation, (130) 146
  multiple paracentesis and *femoral* drainage in (44) 2195
  polycythemia with, (66) 999
  splenomegaly, with cirrhosis of liver and, *operative* treatment, (57) 902
  surgical treatment, (99) 1941
  syphilitic, in asphyxiated newborn infant, emergency paracentesis for, (87) 1667
ASEXUALIZATION See Castration, Sterilization, Unfit; Vasectomy, Vasostomy
ASPERGILLUS niger, research on, (70) 439, (52) 902
ASPHYXIA neonatorum, infant pulmotor in treatment, (116) 1489
ASPHYXIATION, is narcosis due to? (64) 62
ASPIRIN See Acid, Acetyl-Salicylic
ASSOCIATION of American Medical Colleges, 588
  of Military Surgeons of United States meets, 879, 1053
ASTHENIA from functional insufficiency of adrenals, (151) 1738
  general, treatment of, (63) 1405
ASTHENIA, lymphocytosis in nervous disease and, clinical importance of, (122) 231
ASTHMA, (111) 154, (87) 366
  and anaphylaxis, (93) 1326
  and tuberculosis, connection between and tuberculin in asthma, (124) 316
  attenuated types of suppurative sphenoiditis in relation to, (37) 711
  bronchial, cause of, (57) 365
  bronchial, nature and treatment, (74) 712
  bronchial or true, (115) 146
  bronchial, orthodiagraphic study of, (7) 2012
  bronchial, treatment, (46) 66
  *bronchitis and emphysema,* (26) 1936
  bronchoscope in, (31) 510
  bronchotetany and asthmatic bronchitis in infants, (148) 1336
  in children, (48) 66
  lung capillary in, unstable, (33) 807
  nose disease in relation to, (41) 66
  physiotherapy in, (39) 1577

  coli vaccine, 27, 568, 869, 1297, 1900
  colon communis, (91) 1846
  colon communis, agglutination of, *has no diagnostic significance in* infant pathology, (139) 232, (138) 317
  colon communis and uranium nitrate combined to produce experimental chronic nephritis, (8) 431
  colon communis, epididymitis due to (12) 304
  colon communis, epididymo-orchitis, acute, due to, (46) 1666
  colon communis, in urine of patients with cholera, (23) 1665
  colon communis infection of urinary tract in infants and children, (37) 901, (14) 1329
  colon communis infection of urinary tract, nephrectomy, recovery, (1) 514
  colon communis, stomach ulcers produced by intravenous injec*tion of clumped, experimental,* (26) 364
  diphtheria and pseudodiphtheria, differentiation of, (149) 1758
  diphtheria, and scarlatinal infection, (6) 2194
  diphtheria, bacterial sprays fail to destroy, 1393—C
  diphtheria, bile culture medium for, (104) 2198
  diphtheria, determination of, technic for, (109) 440, (158) 1336
  *diphtheria, elective cultivation of,* (143) 73
  diphtheria, human blood-serum as culture medium for, (74) 1413
  diphtheria, improved bile technic for detection of, (109) 440
  diphtheria, in chronic carriers, *(130) 1856*
  diphtheria, in urine, (109) 1668
  diphtheria, *mutation* of, (112) 154
  diphtheria, tincture of iodin applied to eradicate, (162) 1337
  dysentery, carbohydrate reactions of, (123) 367
  dysentery, persistence of agglutinin for, in Danvers Hospital cases, (21) 1843
  fusiform, cultural characteristics, (40) 2190
  fusiform, isolated from blood, case of, (39) 2190
  gas, infection, (120) 996, *1626
  influenza, in disease of genitalia, *(210)* 1672
  lactic-acid, spray, for diphtheria, *392
  leprosy, acquisition of acid-fast properties by filamentary organism cultivated from animal injected with culture of, (37) 1750
  leprosy, and allied bacilli, (35) 2018
  leprosy, cultivation of, (25) 2`6
  leprosy, has it been cultivated? (26) 1575
  leprosy, transmissibility by bedbug, (4) 2011
  megatherium, pneumonic lesions caused by, (47) 1933
  necrosis, epidemic disease in rabbits resembling that produced by, but caused by aerobic bacillus, (25) 1074
  paratyphoid, (80) 228
  paratyphoid *enteritidis group of,* brilliant green broth as specific enrichment medium for, (31) 1403
  proteus, lesions produced by, (44) 2190

BACILLUS, pseudodiphtheria, in urinary tract, *1605
  pyocyaneus vaccine, 27, 869
  subtilis group, assimilation of saccharose by bacteria of, (52) 2195
  tubercle, acid-proofness and non-acid-proofness in saprophytic culture of, chemical conditions influencing, (47) 511
  *tubercle, bovine, in tuberculosis in* children, importance of, (69) 903
  tubercle, dead and living, and their endotoxins in solution in active immunization against tuberculosis, relative value of, *(67) 903*
  tubercle, Gaffky scale for numbering, 359
  tubercle, granules in, (188) 234
  tubercle, in blood, 2246—E
  tubercle, in blood, erythema nodosum with, (23) 2324
  tubercle, in *blood of children,* (105) 230
  tubercle, in blood, only rarely found, (248) 1674
  tubercle, in blood-stream, (109) 70, (94) 314, (90) 1755
  tubercle, in blood-stream in lung *tuberculosis, (103) 154*
  tubercle, in feces, (70) 2016
  tubercle, in skin tuberculosis, (87) 1940
  tubercle, in sputum, detection of, technic for, (165) 378
  tubercle, in sputum, phagocytosis of, (69) 372
  tubercle, infection by, and tuberculosis, distinction between, 2270—ab
  tubercle, inoculation of guineapigs with, technic for, (178) 159
  tubercle, intestine as pathway of infection to, part played by diarrhea, (8) 2194
  tubercle, intraperitoneal lysis of, (17) 2322
  tubercle, of cervix uterus, primary, (23) 1330
  tubercle, portal of entry for, (173) 158
  tubercle, primary infection with, with special reference to thoracic lymph-nodes, (36) 1324
  tubercle, serodiagnosis of, by Alexin fixation, (12) 624
  tubercle, serous pleurisy due to pneumococci and, (13) 368
  tubercle, stain for, (167) 2202
  tubercle, sterilized, action of massive doses of, in subcutaneous *injection,* (174) 1499
  tubercle, true, not often in blood, (86) 1940
  tubercle, types and transitional forms of, (177) 1499
  typhoid, abscess in thyroid with pure cultures of, 21 years after typhoid and followed by acute exophthalmic goiter, (61) 519
  typhoid, colon intermediate group of, with special reference to complement-fixation reactions, (39) 1403
  typhoid, in feces, persistence of, after recovery from typhoid, (146) 910
  typhoid, isolation of, from milk causing typhoid outbreak, *1024
  typhoid, living, in vaccination contra-indicated by danger of making typhoid carriers, 1814-E
  typhoid, otitis media, suppurative, due to, (49) 144
  whooping-cough, and lesion it produces, (9) 219
BACK, injuries to spine and, in coal mining practice, and emergency surgery, (66) 1749

BLOOD, retention of salt in kidney disease with dropsy with subnormal salt content of, (68) 1077
  serum, antitryptic action of, (152) 1336, (140) 1757
  serum, changes which accompany putrefaction of, (139) 1005
  serum, depressor substance in, of patients with exophthalmic goiter, demonstration of, (7) 2271
  serum, diphtheria antitoxin content of human, (116) 2023
  serum, fat-splitting ferments in, (146) 2201
  serum, human, action on guinea pig erythrocytes, (69) 2016
  serum, human, as culture medium for diphtheria bacilli, (74) 1413
  serum, human, injected in epistaxis following turbinectomy in hemophiliac, (8) 142
  serum in gout, (171) 1671, (141) 1757
  serum in hemophilia, repeated injections of, *121
  serum, reaction of, as aid to diagnosis of cancer, (11) 1575
  serum, uric acid in minimum quantities in, and other fluids of body, determination of, new method, (42) 1844
  shutting off, in operations on skull, (62) 716
  smears and blood-count, improved technic, (53) 1851
  smears, parasite of pernicious malaria found at endemic blackwater fever center in, unusual forms of, (10) 624
  specific gravity of, (29) 1665
  spirochete, new, found in human, (33) 226, 2170
  spirochete of human, new, and its bearing on pathology, (44) 65
  spleen in relation to hemolytic jaundice and destruction and degeneration of, (20) 2322
  -stain for tissues and, improved, (61) 2278
  -stain, Harlow-Hayhurst, 2000—C
  -stain, invariable, *1627
  -stain, medicolegal examination of, (186) 234
  studies in constipation, 100, (49) 1845
  sucre virtuel in freshly drawn, supposed existence of, (82) 1325
  sugar in, (118) 1417, (175) 1946
  sugar in, and adrenals, (58) 228
  sugar in, effect of feeding starch on, 1819—E
  sugar in, estimation of, (117) 1942
  sugar in, in children, (125) 2112
  sugar in, in diabetes on different diets, (117) 1496
  sugar in, in human diabetes, 418—E
  sugar in, Kowarsky's test, (101) 1334, 1921, 2200
  sugar in, small amounts of, technic for determining, (101) 1334
  sugar in, with chronic nephritis, (116) 1942
  -supply with gangrene of foot, test for, (163) 446
  syphilitic patients and, (129) 1943
  -test, clinical and microchemical, improved, *1897
  -test for syphilis, Tschernogubow's, 1921
  test tube reactions of elements of, differential, (164) 2202
  thorium x in disease of, (129) 1418
  toxic action on, and virulence of streptococci, relation between, (136) 523
  transfusion by Crile's technic after serious hemorrhage from urinary apparatus, (36) 626
  transfusion, direct, technic, indications and advantages of, (175) 722
  transfusion, direct, with self retaining tubes, simplified method of, *490
  transfusion from pregnant woman, uncontrollable vomiting of pregnancy arrested by direct, (90) 439
  transfusion in extra-uterine pregnancy, (183) 147
  tranfusion, new and simple method, *117
  transfusion of fresh normal, method for, (94) 899
  tubercle bacilli in, (109) 70, (95) 314, (90) 1755, 2246—E
  tubercle bacillus in, of children, (105) 230
BLOOD, tubercle bacillus only rarely found in, (248) 1674, (86) 1940
  urates in, test for, technic for, (147) 73
  urea in, as test for kidney functioning, (176) 1499
  urea in, new test for determination of, (80) 1325
  urea in, variations of, with practical method for its determination, (72) 994
  uric acid disappearance in, in gouty after treatment with radioactive substances, (144) 2201
  uric acid in, urinal test for, (96) 313
  vasoconstrictor substance, new, isolated from adrenal cortex and, *2136
  venous, segregation of, in circulatory disturbances, (104) 1756
  -vessels, anastomosis of, mechanical device for, (94) 1934
  -vessels and heart disease, prognosis in, (72) 2388
  -vessels and heart symptoms, importance of treatment in diabetic coma and stage preceding, (71) 904
  -vessels, axillary, arteriovenous aneurysm of, of thirty years' standing, (28) 2018
  -vessels, balneotherapy in disturbances of heart and, (70) 373
  -vessels, calcareous deposits in, (59) 1331
  -vessel changes consequent on nervous lesions, (52) 433
  -vessel changes secondary to nephritis, 1399—ab
  -vessels, coronary, effect of nitrites on, (94) 1334
  -vessels, dietetics in diseases of heart and, (94) 440, (51) 518
  -vessels, fascia grafts to close, (195) 1760
  -vessels, femoral, arteriovenous aneurysm of superficial, *2155
  -vessels, how undissolved particles can traverse walls of lymph-vessels and, is a vexed question, 1461—E
  -vessels, hypoplasia of, delivery with, special care necessary in management of, (69) 628
  -vessels in heart, abnormal positions of great, comparative anatomy of bulbus cordis with special reference to, (6) 2323
  -vessels in shock, state of, (43) 2107
  -vessels, kidney, injuries to, (218) 1672
  -vessels, reflexes of, (118) 1004
  -vessels, roentgenoscopy of heart and large, (106) 440
  -vessels, strophanthin in diseases of heart and, (256) 1674
  -vessels, surgery of, (98) 154
  -vessels, suture of, end-to-end, by technic that enlarges lumen, (86) 2197
  -vessels, suture of, in readiness for emergencies, necessity for mastering technic for, (158) 1006
  -vessel suture with aneurysm, (90) 718
  -vessels, suturing, absorbable flat rings to aid in, (53) 1410
  -vessels, technic for obliterating, (126) 1418
  -vessels, therapeutic venous congestion in treatment of diseases of heart and, (100) 1415
  -vessels, venous blood-pressure as influenced by drugs in treatment of heart and, *388
  viscosity, diagnostic importance of determining, in surgical work, (111) 1334
  viscosity, and leukocytes, (151) 524
  viscosity, clinical importance of, (57) 151
  viscosity, estimation of, (110) 154
  -volume, effect of altitude on, (32) 1937
  -volume in normal and nephritic animals, regulation of, (23) 1074
BLOOMER'S catarrh remedy, 616—P
BLUE litmus, action of saliva on, 507
  spot, Mongolian, so-called, (66) 1493
BOARDS, medical, state, federation of, chief needs for and functions of, 1558
  Health: See Health, Boards of
BODY, examination which must be allowed after exhibiting portions of, 140—MI

BODY fluids, urobilin and urobilinogen in, significance of, (75) 1001
weight of newborn infant, influence of physical and social relations of mother on, 135
BOILS, treatment, 1535—ab
BOLT, Dr R A, honored, 48
BONE, animal, absorbable, fixation apparatus made of, *333
autoplastic operation in pseudarthrosis, (179) 722
cancer, fracture in, spontaneous, (14) 1569
cavities and fistulas in mouth, treatment, (140) 1005
cavities, fat implants as filling for, (59) 903, (79) 1001
cavities, thermocautery to precede filling of, (182) 1338
clamps, external, versus internal bone plate in operative treatment of fractures, *930
cysts, (130) 523
cysts in long, solitary, (129) 1669
echinococcosis, (172) 378
endotheliomas in, primary, two cases, (142) 1005
filings, danger from, (43) 622
flap slightly askew, decompressive craniotomy with primary plastics by twisting, (76) 629
foot, influence of operations on later growth and functioning of foot, (63) 903
forearm, anterior dislocation at elbow, complete, (181) 147
formation in human penis, (25) 220
fractures of long, reduction of fragments in, at open operation, (34) 2101
fracture of long, reduction of fragments preliminary to internal splintage in, (18) 1746
fragility of, (113) 1334, (104) 2111
grafts, fate of, (100) 307
hand, dislocation of, (95) 718
hyoid, finger elevation of, in general anesthesia, Chevalier Jackson method, (36) 2101
infectious diseases of children and changes in, (184) 1672
inflammation of, acute, (37) 311
influence of castration on growth of, after sexual maturity, (176) 1758
ivory prothesis implants with screw-thread in joints and, eight cases, (81) 1078
joint and, cases, (132) 1936
lesions of small-pox, (117) 367
lesions, treatment, (4) 623
lesions, unusual, 1742—ab
long, negative pressure in, in dogs, (90) 814
marrow and leukocytes in carbon dioxid poisoning, (99) 1581
marrow, granulating inflammation of, experimental and clinical research on, (109) 2022
marrow, red, in femur, (25) 2324
marrow, stipple red cells in, (134) 908
metacarpal, cyst of fifth, (22) 1746
obstruction of postnasal orifices, congenital, (19) 1324
physiology of, in relation to surgery, (39) 364
plastic and graft operations on spine for Pott's disease, results, *1780
plates, excision of knee for tuberculosis with and without, end results, (17) 432
regeneration, clinical aspects of, from study of union of fractures, (30) 2014
regeneration from periosteum, (138) 1328
roentgenography in diseases of, 1742—ab
roentgenography in prognosis of lesions, value of, 1659—ab
roentgenoscopy of joints and, as aid in orthopedic surgery, (91) 1940
scaphoid, of foot, isolated disease of, in children, (132) 2104
shortened, of leg, lengthening by operation, (109) 514
substance, changes in structure of, in osteomyelitis, their causes, (143) 1669
sunlight therapy in disease of, (22) 2271
surgery, problems in, 1657—ab
syphilis, 1743—ab
syphilis of joints and, in children, (38) 311
syphilis of joints and, in children, differential diagnosis, (50) 492
syphilis of skull, (52) 1748
BONE, temporal, examination of, from 120 individuals regarding question of symmetry in health and disease, (2) 142
transplantation, (91) 223
transplantation for flail joint produced by inflammatory destruction of joint, (95) 2016
transplantation of joints and, (41) 1410, (87) 1494
transplantation to close defects in skull where large areas have been destroyed by trauma or disease, new methods, (25) 1747
tuberculosis and trauma, (117) 63
tuberculosis, end-results, 1564—ab
tuberculosis of joint and, conservative treatment, increasing tendency to, (110) 70
tuberculosis of joint and, direct sunlight in, (146) 73
tuberculosis of joint and, roentgenotherapy of, (74) 904
tuberculosis of joint and, treatment, (86) 68
tuberculosis of long, (94) 1940
tuberculosis of lung or, sporothricosis simulating, (72) 1753
BOOK marker, reflecting, for teaching readers how to avoid eye-strain, (115) 899
on treatment of electric shock valuable result of cooperative effort of physicians, surgeons and electrical engineers, 1637 E
BORDET-GENGOU vaccine, bacillus of, 2158
BOSKANO'S cough syrup, 616—P
BOSTON HERALD, attitude taken toward antivivisection by great mass of newspapers typified by editorial in, 2248—E

EAR: See also Labyrinth
EAR, abscess of frontal lobe of brain originating in, (15) 1323
  abscess, temporal, sub-periosteal, originating in, without intra-osseous suppuration, (60) 1934
  affections dependent on visceral lesions and functional nervous disorders, (103) 436
  and nose manifestations of influenza, diagnostic features of, (20) 142
  aurometer for watchinng progress in cases of, (99) 2104
  brain abscess originating in, (33) 2107
  diphtheria, local, after piercing, (121) 1004
  disease, acute, treatment by general practitioner, (89) 623
  disease of upper respiratory tract and, as affecting military efficiency, (34) 1850
  drum, perforated, may be responsible for sudden death in water, (39) 2325
  ductless gland extracts and affections of, (60) 2103

EAR, eye manifestations in diseases of nose and, which probably indicate involvement of sympathetic nervous system, (12) 1323
  gauze packing in canal of, (62) 1934
  hallucinations of hearing and diseases of, (121) 63
  hearing following radical operation on, Thiersch graft versus tampon, *1211
  Hiss leukocyte extract in complications of surgery of nose and, (56) 1934
  industrial accidents and, (52) 228
  internal, (86) 2021
  internal, electric tests of, (21) 2275
  middle, deafness, obstructive, chronic, *1206
  middle, disease, deafness from, diathermia in, (73) 628
  middle, inflammation of, acute, (142) 1847
  middle, suppuration of, acute, (61) 1405
  middle, suppuration of, acute, its *neglect* and proper treatment, (5) 142
  middle, suppuration of acute, sinus abscess as complication to, (43) 902
  middle, suppuration of, danger signals in, (21) 620, (27) 1570
  middle, tuberculosis of, primary, (74) 223, (4) 225, (22) 1324
  muscles of, trained in deafness, (60) 2195
  nose and throat diseases, clinics of Britain for, (29) 901
  regeneration of membrana tympani, (73) 223
  scarlet fever and, (104) 230
  speculum, illuminating, *491
  systemic disease in relation to local disease of, (46) 2015
  temporosphenoidal abscess originating in, operation, recovery, (23) 1324
  throat and, clinics, British, historically considered, (28) 901
  traumatic atresia of external auditory meatus of left, with mastoid complications, (39) 1487
EARACHE, (139) 1072
  cause and treatment, (89) 366
  relief of, and induction of operative anesthesia by infiltration of auriculotemporal and tympanic nerves, (24) 1487
EARNING capacity in nervous conditions, estimation of, (110) 1496
EARTH-CLOSETS, power of municipality to deal with, 1926—Ml
EAU DE QUININE, Pinaud's, 1476
ECHINACEA, value of, 2038
ECHINOCOCCOSIS, (1) 623, (2) 899, (41) 1492
  bones, (172) 378
  cholecystenterostomy for obstruction of common bile duct due to, (15) 899
  *liver, spontaneous* suppuration of, (93) 1667
  liver, true total enucleation of, (7) 1490
  lung, differential diagnosis, (117) 1756
  lung, operation for, (154) 1944
  lungs, (54) 2278

ECLAMPSIA, (129) 1035, (109) 1574, (37) 2014
  a toxemia possibly originating in breast, (19) 306
  an anaphylactic disease, 2255
  and post eclamptic psychosis, (81) 144
  cesarean section for, (5) 623
  diagnosis and treatment, *(41) 143*
  dilatation of os uteri, instrumental, advantages of, *(136) 1944*
  expectant treatment, (134) 1335
  experience with 158 cases, (112, 127) 631
  present status, (88) 313
  prognosis, (4) 991
  puerperal, cause and treatment, 990—ab
  puerperal, emptying uterus in, (5) 895, (101) 998
  puerperal, epidemic, (44) 844
  puerperal, four times, (76) 1939
  puerperal, management of, (2) 63
  puerperal, medical and surgical treatment, (15) 305, (100) 9[illegible]5
  puerperal, morphin in, (74) 43
  puerperal, treatment, (31) 998
  puerperal, veratrum viride in, (3[illegible] 1844
ECLAMPSIA, strotherapy, (156) 2025
  toxemia of pregnancy with special reference to, (128) 2017
  treatment, (179) 159, (104) 1080, *(121) 1757*
  treatment in wage-earners' homes, (119) 631
  veratrone for, (26) 1848
ECLIPSE, scotoma from watching, (178) 74
ECTOPIA cordis, case of, (11) 515
  lentis, complete bilateral aniridia, pathologic cupping of discs, (127) 1072
  testis, (3) 712
ECZEMA, acute, in course of syphilis, (100) 1846
  as expression of exudative diathesis in infants, (117) 1334
  descendens, (139) 146
  differential diagnosis of syphilis of hand, psoriasis and, (56) 2103
  in children, diet for, (135) 232, (134) 317
  in children, fatal cases, (15) 1329
  in children, skin reaction, specific, none in, (237) 1673
  infantile, (81) 2103
  parapsoriasis in relation to, (18) 142
  prevention and treatment, (26) 2107
  roentgenotherapy of, (74) 994
  toxic, and latent erysipelas, (89) 1940
EDEMA and polyneuritis in native African troops, (71) 2109
  angioneurotic, horse-serum injections cure for, (53) 62
  angioneurotic, urticaria and purpura of hands and feet in nursing infant, *18
  chronic, operative treatment, (115) 1003
  *eyelids, as sign of maxillary sinusitis,* (155) 233
  fetus, (23) 714
  heart, alkali and salt in, (26) 306
  induced by large dose of alkali, (147) 318
  legs, familial, congenital, (166) 2025
  paroxysmal, *of lungs,* (9) 368
  soda (147) 318 (101) 440
EDESTIN and peptone in diagnosis of cancer of stomach, value of, (15) 1402
  immunity reactions of, (44) 511
EDUCATION See also Colleges, Schools University
EDUCATION, foundation of, (91) 995
  Howard University adopts higher requirements, 216
  medical, and medical profession, (104) 1846
  medical, and students' ideals, moot questions in, (68) 2193
  medical, chemistry in, *1805

INSTITUTE, Kaiser Wilhelm, for experimental therapy, 1915
INSTITUTIONS, vast increase in number and variety of, is chief factor in reshaping modern society, (88) 1573
INSTRUMENT: See also Apparatus
INSTRUMENT, antrum knife, new, (19) 1487
  audiometer, improved, (67) 994, (99) 2104
  azotometer for quantitative determination of urea, uric acid and purin bases in urine, (137) 2024
  blood-transfusion, self-retaining tubes for direct, simplified method, *490
  bowel doormaker, technic of operation for short-circuiting intestine, (93) 366
  coin-catcher for removing coins from esophagus, *491
  colorimeter, simplified, *2064
  cystoscope and evacuator, combined, (86) 712
  duodenal and small intestine, new, (107) 145, (67) 216
  duodenal, improved and new, technic of speedy intubation of normal duodenum, (80) 1663
  electric devices for applying moist heat in gynecology and laparotomy, (67) 1077
  electrically propelled rotary chain-saw and automatic trephine with accessory, (40) 2014
  endoscopic syringe, (68) 994
  energometer, (124) 375, (82) 250
  equipment for physiologic laboratory, inexpensive, *2065
  eyelid elevator, (120) 2017
  fixation forceps, (118) 899
  for measuring visual-field defects, new, (1) 2189
  for normal coagulation of blood, (9) 1745
  forceps, *769, (22) 997
  glass cylinders for transfusion, *1628, (12) 2189
  hemostat as safety blade holder, (51) 2273
  kidney forceps, new, *2064
  LaForce adenotome, modified, (152) 147
  ligature scissors, (118) 1489
  manometer and safety-valve for operation of artificial pneumothorax, *1629
  myringoscope, *2065
  pipet, *769
  perimetry, new, *277
  perineal retractor, self-retaining, (101) 1072
  pleximeter, double, (181) 378
  pneumothorax manometer, *771
  retractor for abdominal contents during peritoneal closure, new, *2066
  retractor for superficial dissections, self-retaining, small, (73) 1573
  retractor, self-retaining, for use in perineorrhaphy, (122) 513
  salvarsan needle, (82) 1071
  scalpel blade, detachable, *1535
  Skene's retention catheter, (154) 1327
  sphygmobolometer, simplified and improved, (61) 808, (46) 1851
  sphygmomanometer, clinical, pocket, new, (64) 512
  spreader to hold open suppurating process, (128) 632
  suction tip for aspiration in abdomen operations, (24) 1746
  surgical care of, (60) 999
  tariff bill and, 1060—ME
  surgical, Pompeian, (87) 1406
  tonsil knife for tonsillectomy, special, (115) 1749
  tourniquet for giving salvarsan intravenously, simple, *2066
  tourniquet, simple, *965
  urethroscope, irrigating, direct view, for diagnosis and treatment, (81) 1071
INSUFFLATION, Intratracheal: See also Anesthesia, Intratracheal Insufflation
INSUFFLATION, intratracheal, anesthesia, (38) 65, (30) 364, *839
  intratracheal, Meltzer's experiences with, (134) 632
  intratracheal, tubes, insertion of, technic, (123) 1846
INSURANCE act and British Medical Association, 1469, 2168
  act, British, benefits of, 295—ME
  act, British, effect on proprietary prescribing, 872—E
  act, defects of, their remedy, (12) 436
  act, experiences of medical adviser under, (4) 308
  act, national, 209, 289, (3) 436, 1548, (94) 1573, (26) 1844, 2253
  act, physician imported in connection with working of, 1914
  act, profession and public, (6) 515
  companies, educational value of cancer statistics to public, medical profession and, 2099—ab
  companies, unfair demands on physicians by, 212—C
  health, and workingmen's compensation in Roumania, (117) 2111
  legislation, German, and German hospital, (9) 809
  life, and syphilis, (60) 1851
  life, directors' meeting, 693, 1912
  life, *examinations*, (65) 1325
  life, traumatic thrombosis of inferior vena cava in relation to, (139) 443
  medical, abroad, 2314—ME
  medical, in Germany, 1834—ME
  national, in its literal sense, (1) 2105
  societies and physicians, struggle between, 2254
  societies, struggle by German medical profession to preserve its freedom from control by, 2163-E
INTERNATIONAL Association of Medical Museums, 355, 612
  Association of Orthopedic Surgery, 697
  Conference on Tuberculosis, 614
  Congress of First Aid, 1731
  Congress of Neurologists, Psychiatrists and Psychologists, organization of, 976
  Congress of Refrigeration, third; 1054
  Congress on School Hygiene, 355, 499, (129) 2017
  Exposition of Safety and Sanitation meets, 131
  health office in Jerusalem, 613
  Medical Congress, 133, 208, 289, 609, 685—E, 891—ab
  Medical Congress, address on heredity at, 697
  Medical Congress, address on medicine at, 610
  Medical Congress, address on surgery at, 610
  Medical Congress and women, 612
  Medical Congress, candidates for prizes of, 134
  Medical Congress, commercializing the, 688—E
  Medical Congress, Ehrlich's address in pathology at, 610
  Medical Congress, *medical history* at, (29) 370
  Medical Congress, museum of, 894—ab
  Medical Congress, section on diseases of children, 801—ab
  Medical Congress, section on medicine at, 612
  Medical Congress, section on obsterics and gynecology at, 891—ab
  Medical Congress, section on surgery, 797—ab
  Medical Congress, section proceedings, 612
  Medical Congress, social events, 611, 696
  Medical Press Association, 611
  Skin and Cancer Institute of Denver claims a cancer cure, 2248—E
  Society for Sex Investigation, foundation of, 2254
INTERSTATE Commerce, Owen introduces bill for inspection of trains, depots, vessels, etc., used in, 297—ME
  quarantine regulations regarding water and ice supplied by interstate carriers, 881—ab
INTESTINE abnormalities, roentgenoscopy of, (32) 2018
  amebae of man, morphology of, (15) 2194
INTESTINE amebiasis, chronic, without dysentery, (41) 1324
  anastomosis and abdominal incisions in cancer of colon, (21) 226
  anastomosis, aseptic basting stitch method in, (120) 1846
  anastomosis without suture, device for, (53) 365
  angulations and adhesions due to enteroptosis and chronic constipation, relation of, (51) 207
  angulations and kinks associated with stasis, (38) 437
  anomalies in, lower, development of, (127) 1418
  as pathway of infection to tubercle bacillus, part played by diarrhea, (8) 2194
  bacillus lactis bulgaricus implanted in, for infantile diarrhea, *164
  bacteria and auto-intoxication, (25) 2275
  bacteria in pellagra, (3) 59
  bacteriology in health and disease, certain aspects of, (134) 224
  bacteriology of intestinal disease in infants, (124) 70
  cancer in boy, (66) 1939
  cancer in large, outside of rectum, (76) 2109
  cancer in lower, aspect of first beginnings of, (141) 232
  cancer of small, primary, (77) 1667
  cancer of stomach and, (28) 1844
  complications with lung tuberculosis, improvement after radical operation and salvarsan, (52) 1077
  disease of cecum and large, (167) 1758
  disturbances consecutive to gastro-enterostomy, (19) 2324
  diverticula of large, (51) 1492
  fibroma of, eventuating in intussusception and intestine obstruction, (14) 2101
  fistula in dog, experiments with, (119) 1581
  gas cysts of, (18) 220, (51) 1938, (75) 2109
  hemorrhage in tuberculosis, (90) 1071, (94) 2103
  hemorrhage in typhoid, (34) 2014
  hyperthyroidosis originating in, *2145
  ileus with congenital malposition of large, (134) 818
  implants, action of gastric juice on (136) 156
  incarceration, retrograde, of, (60) 2278
  infant born with whole intestine outside abdomen, appendectomy successful, *199
  infection and gastro-intestinal intoxication in infants, (45) 1844
  infection, chronic, and water, (23) 1570
  inflammation of male genitalia and large, and functional neuroses, connection between, (108) 631
  influence of opium on stomach and, (153) 157
  injuries, hernial sac in relation to concealed, (33) 1069
  instruments for duodenum and, new, (107) 145 (67) 716
  intoxication, (22) 437, (86) 1078, (70) 1749, (34) 1844, 2070—E
  intoxication and intestine infection in infants, (45) 1844
  intoxication and sympathetic nervous system, (103) 718
  intoxication and thyreotoxicosis, (122) 1574
  intoxication in dermatology, (40) 65
  intoxication in infants, dextrose solutions in acute, 2188—ab
  intoxication in relation to eye, (36) 711
  intoxication, influence of daily habits in causation of, (47) 902
  intoxication in relation to obstetrics and gynecologic affections, (29) 1330
  intoxication, metabolism in dyspepsia and (157) 722
  intoxication of children, (85) 366
  intoxication, resistance to, and complexion, correlation between, 273—ab
  intoxication, treatment of, (108) 2199
  intoxication, urinary products of, (11) 368
  intoxication with constipation and surgical treatment, (97) 995
  invagination, (120) 230, (164) 233
INTESTINE invagination in adults from ascarides or lipoma, (98) 229
  invagination in children, (75) 2196
  invagination of small, acute, recurrent, fatal cases, (105) 1496
  irrigation of lower, in typhoid, 214
  motor functioning of, (58) 519
  mucosa of, atrophy of, with pernicious anemia, (155) 2202
  neurosis of, enterospasm is, 219—ab
  obstruction, (110) 367, (28) 710, 1323—ab, (25) 1330, (53) 1331
  obstruction, acute, cause of death in, (8) 1936
  obstruction, acute, treatment, (81) 1406
  obstruction and inflammation in Meckel's diverticulum, (20) 1850
  obstruction and scurvy, (27) 2194
  obstruction, consequences of, 1988—E
  obstruction due to gall-bladder calculi, (124) 1490
  obstruction, fibroma of intestine eventuating in intussusception and, (14) 2101
  obstruction in rabbit, (58) 223
  obstruction, postoperative, acute, (30) 1844
  obstruction, retroperitoneal hematoma as cause of, (58) 1076
  obstruction, seventy cases, (13) 2101
  obstruction, unusual cases, (125) 1847
  occlusions of esophagus and lesser, congenital, (31) 370, (23) 901
  occult hemorrhage in stomach or, (38) 1075
  oxyuris vermicularis, diagnosis and treatment, (155) 722
  parasites, 1922, (86) 2016
  parasites, encountered in 500 autopsies, (105) 1935
  parasites in Georgia, most prevalent, (44) 1662
  parasites, prevalence in Philippines, (4) 363
  passage of barium sulphate in suspension through, *1419
  passage of stains through, after subcutaneous injection, (99) 1334
  pathologic physiology of, (46) 150
  phlegmonous disease of, (174) 1946
  physiologic rest of large, complete, for certain ulcerative and obstructive lesions of organ, value of, (90) 307
  polypi, multiple of, (120) 1334
  putrefaction, quantitative estimation of, (62) 372
  reflex contraction of large, from impulses emanating from stomach, (33) 516
  reflexes in large, therapeutic, (61) 1077
  resistance of nerve cells to anemia a proof of hardness of nerve cells in, 2244—E
  roentgenograms of, (52) 307
  roentgenoscopy of disease and adhesions of large, (79) 1078
  roentgenoscopy of obstruction in small, (93) 374
  rupture of, traumatic, operation, recovery, (106) 63
  sand in, *238
  sarcoma, (92) 718
  sarcoma, acute invagination of ileum secondary to, (145) 1327
  sarcoma, giant-celled in, in infant, (179) 1672
  sarcoma of small, (119) 368, (100) 1072
  short-circuiting, technic of operation for, (93) 366
  starch bacteria in human, (168) 1499
  stasis, (40) 221
  stasis, chronic, (88) 397, (53) 434, (90) 712, (82) 1406, (41) 1488, 2011—ab, (1, 2) 2017
  stasis, chronic, orthopedic principles in abdominal visceroptosis and, (86) 307
  stasis, malpositions of abdominal viscera in, (40) 711
  stasis, postoperative, and intra-abdominal, use of oil, (39) 1844, (85) 2103
  stasis, surgical aspects of from anatomic point of view, *639, (15) 1936
  stasis, surgical theories of, (93) 2194

INTESTINE stenosis, congenital, (127) 2023
  stomach and, unrecognized interrelations between, 350—E
  surgery of large, (34) 370, (53) 715
  sutures, experimental study, (52) 1324
  syphilis of small, congenital, with *spirochetes, histology of,* (150) 444
  transplantation after extensive excision of sigmoid, experimental, *544
  ulcers and cancers of, surgical treatment, (56) 512
  ureters implanted into large, *1691
  volvulus of large, (80) 1078, (142) 1669
  volvulus of *small complicating* general peritonitis, recovery, (39) 810
  worms frequent cause of disturbances of, (113) 1081
INTIMA, structure of, in atherosclerosis, (212) 1672
INTUBATION, (118) 996
  contact ulceration following O'Dwyer's medicated tube in treatment, (113) 1756
  in membranous croup, (68) 1749
  peroral, in upper respiratory passages and esophagus, (92) 2281
  temporary, to cure disease of lacrimal sac, (247) 1874
  with Meltzer's insufflation anesthesia technic for, (41) 2277
INTUSSUSCEPTION, (126) 64, 2097—ab
  acute, (15) 1490
  complicated by measles and bronchopneumonia, operation for, (6) 1490
  diagnosis and treatment, (55) 1070
  fibroma of intestine eventuating in intestine obstruction and, (14) 2101
  in children, diagnosis, 1924—ab
  in infants, (31) 2324
  *in infants,* absence of sausage-shaped tumor and mass per rectum in, (98) 1326
  invagination of Meckel's diverticulum associated with, (12) 1068
  lipoma of descending colon causing, (70) 1405, (125) 1847
  roentgenoscopy of, (7) 803
  stomach and doudenum, due to gastric polypus, (140) 1327
  with atypical symptomatology, (26) 432
IODIDS, (62) 1749
  potassio-mercuric, an antiseptic, (86) 1071
IODIN and ether test for bile pigments in urine and blood, (133) 155
  *and ichthyol, combined,* in furunculosis, (37) 2325
  and silver stains, removal from fingers, 704
  applied to eradicate diphtheria bacilli, (162) 1337
  aqueous solution of, for varicose veins, 2266—ab
  blindness following fracture or, sudden, (77) 1846
  centenary of discovery of, 2880
  elimination in body, action and two types of, (151) 910
  *fumes in local treatment,* (55) 311
  idiosyncrasy, (86) 1573
  in aseptic vaccination, (14) 2017
  in erysipelas, (179) 1338
  in laparotomy, (10) 2101
  in *tuberculosis of joints,* internal and external use of, (34) 2018
  in urine, test for, (56) 812, (80) 1939, (94) 2197
  nascent, intensive, administration in lung tuberculosis, (56) 1531
  sterilization is harmless for operator, (111) 1003
  sterilization of children's skin, (40) 227
  sterilization of skin, (117) 440, (109) 1489
  sterilization, removal of discoloration left by, (95) 2282
IODIZED gauze for first-aid packet, (127) 1750
IODOFORM and benzoyl chlorid in lung tuberculosis, (15) 64
  and tuberculin in tuberculosis, (83) 373
  in lung tuberculosis and pneumonia, intravenous injection of, (121) 1855
IONIC medication, (15) 996
IONIZATION for corns and warts, (35) 1750
  Roentgen rays, in connection with, (26) 1750
IONS as factors in climate and therapeutics (111) 1080
IOWA medical news, 127, 287, 353, 419, 691, 877, 1638, 1820, 2075 2250
  state board June report, 982
IPOMOEA, root of, from Rhodesia, examination of, (6) 368
IRIDECTOMY and fistulas of cornea, (91) 513
  optic, (30) 510
IRIDOTASIS, operations for glaucoma, (116) 712, (39) 1070
IRIS, defective, (60) 228
  *gumma of, after use of salvarsan,* (115) 224
  hecterochromia iridium, (85) 513
  nerve plexus of, persistence after excision of certain ganglia, (13) 2017
  sarcoma of, (4) 899
IRISH clinicians of 19th century, (11) 619
IRITIS, gonorrheal, what general practitioner should know about, (70) 623
*IRON, colloids of,* (33) 150
  hypodermic administration of, 1476
  in chlorosis anemia and status lymphaticus, technic for, (173) 1499
  metabolism of, and splenectomy, 777—E
  regeneration of blood under, (116) 230
IRRIGATION basin, new, (121) 2017
IRRITATION, chronic, caused by fumes and dust produced in process of manufacturing tin plates, (38) 810
ISIGWEBEDHLA, a fictitious native disease, (4) 2194
ISO-ELECTRIC points of human milk and milk of various animals, (156) 722
ITALIAN Physico-Chemical Academy, 1737
IVORY *plant for restoration of* joint, (144) 157
  peg in fracture, (139) 1669
  plates and screws, holding fractures with absorbable material, *1514
  prothesis implants, with screw-thread in bones and joints, eight cases, (81) 1078

J

JABOULAY button, gastro-enterostomy with, (54) 1938
  death of professor, 1914
JACKSON and Brunings methods of broncho-esophagoscopy, technic of, brief comparison, (126) 1327
  Chevalier, method of finger elevation of hyoid bone in general anesthesia, (36) 2101
  J Hughlings, of London, certain features of work of, (24) 364
JACKSON'S MEMBRANE, *248, *635
  a normal structure, (30) 1747
JAMES-LANGE theory of emotions, *1675
JAPAN, tuberculosis and anti-tuberculosis work in, (39) 2273
JAPANESE, food of, (35) 2325
JAUNDICE, catarrhal, behavior of duodenum content with duodenal processes and, (85) 1414
  chronic, and chronic pancreatitis, research on, (135) 909
  epidemic of, (18) 309, (31) 2014
  family, chronic, two instances, (9) 2012
  fever with, (15) 624
  following abortion, (69) 1753
  hemolytic, (91) 629
  hemolytic, and ankylostomiasis, pathologic anatomy of, (72) 439
  hemolytic, congenital, (101) 154
  *hemolytic, congenital, pathogenesis* and pathologic anatomy, *1586
  hemolytic, local hemorrhage causing, (30) 516
  hemolytic, spleen in relation to blood destruction and regeneration and to, (41) 1932, (20) 2322
  infectious, acute, in children, (84) 712
  resisting powers of red blood corpuscles in anemia and, (168) 233
JAW, ankylosis of, due to cicatricial formations in cheek, palate mucous membrane flaps in, *245
  contraction and expansion of upper, pathologic and therapeutic possibilities of, (130) 2017
  deformity of lower, correction of, (94) 718
JAW, granuloma of, (14) 997
  movements of lower, in pronunciation of vowels, (118) 1581
  osteitis fibrosa cystica of lower, 1657—ab
  prothesis, simple, after removal of great part of lower, (31) 2107
  sporothrix process in upper, (102) 1668
JEJUNUM, sarcoma of ileum and, primary, (124) 1855
  ulcer in, peptic, postoperative, radical operation for, (75) 312
JEQUIRITY, epithelioma of face healing under treatment with active principle of, (159) 1499
JERUSALEM, health problems in, 1989—E
JILES, H J, and Dr Cook & Company, 293—P

NEWSPAPER and psychiatry, (108) 69
attitude taken toward antivivisection by great mass of, typified by editorial in Boston Herald, 2248—E
comments on public health topics, 789—ME
comments on sex hygiene, 1477—ME
country, irregular practice of medicine as viewed by, 126—E
refuses quack advertisement, 775—E
should not advertise means of committing suicide, 1059—ME
NIGHT medical service at police station, twenty years of, (167) 1006
soil incineration in cantonments, (19) 2017
NINHYDRIN, 1377
and epiphanin reactions, 788
or triketohydrindenhydrate reaction, bearing in anaphylaxis, 415—E
reaction as test for amino-acids in serum of nephritics and others, negative results, *1456
test for peptone, 2313—C
NIPPLE, tuberculosis of, (66) 1753
NISSL'S granules in ganglion cells, chemical composition of, (111) 1756
NITRATES, can animals utilize? 204—E
putrescibility of sewages in relation to, (30) 1403
NITRITE destruction as presumptive test for determination of water pollution, (46) 511
effect on coronary blood-vessels, (94) 1334, (58) 1748
poisoning from bismuth paste, (118) 230
NITROGEN, amino-acid, in urine, determination of, (11) 2321
amino, aliphatic, gasometric determination of, in minute quantities, (43) 1747
amino, in tissues, determination of, (54) 2015
and ammonia-nitrogen in urine, clinical tests for estimation of total, *87
atoms, asymmetric, effect on physiologic activity, some examples of, (76) 898
colloidal, of urine, 778—E
colloidal, Salkowski-Kojo's, in urine in diagnosis, (52) 2278
compounds in urine in fever, (138) 1005
content of malignant tumors in man, (34) 64
estimation of total, (109) 436
extractives in uterine muscle, (60) 1938
in urine, (58) 1077
metabolism, effect of changes in circulation of liver on, (35) 433
metabolism, endogenous, effects of acid and basic salts and of free mineral acids on, (63) 2015
metabolism, endogenous, influence of benzoic acid on, (65) 2015
metabolism, endogenous, influence of fat feeding on, (64) 2015
metabolism in diabetes, (95) 1334
non-protein, of blood in nephritis and allied conditions, (45) 992
or non-nitrogenized food plus carbon, oxygen, hydrogen group, (69) 808
output in heart and kidney disease, (48) 1077
partition of urine, liver insufficiency estimated from, (16) 2323
poisoning, (108) 1326
rate of elimination influenced by diet factors, (38, 40) 1747
residual, behavior of urea and, in blood with nephritis, (103) 229
retention, non-protein, and phenolsulphonephthalein excretion in experimental uranium nephritis, (6) 1401
NITROGENOUS bodies and urea in blood in typhoid, (67) 311
products, absorption of, (56) 62
waste products in blood in nephritis, (17) 1487, (15) 2189
NITROGLYCERIN, when and how to use, *118
NITROUS-OXID anesthesia: See Anesthesia, Nitrous-Oxid
NOCARDIA, infection with, (23) 1487
NOGUCHI'S demonstration in London, 1729

RESONATORS with special reference to Schaefer's apparatus, (92) 63
RESORTS, health, British, international aspects of, (8) 1073
RESPIRATION and pulse, influence of body length on frquency of, (52) 1498
  arrest of, during deep inspiration, (136) 909
  artificial, (121) 720
  artificial, during operations in thorax, (42) 2277
RESPIRATION, *artificial, respirator an appliance for resuscitation by producing enforced*, (66) 808
  artificial, to prevent danger of open pneumothorax, simple practical means for, (102) 1940
  as aid in circulation, (87) 629
  first, cause of, (45) 897
  in heart disease, (114) 1668
  influence of mental attitude in treatment of diseases of organs of circulation and, (32) 807
  movements of walls of thorax during, (125) 2199
  normal, pauses in, (110) 1416
  rhythm, abnormal, (64) 2108
RESPIRATOR, appliance for resuscitation by producing enforced artificial respiration, (66) 808
RESPIRATORY passages, peroral *intubation in esophagus and upper*, (92) 2281
  resonance in lungs, (73) 1414
  system, mine conditions deleterious to, 1557
  *tract, disease of ear and upper, as affecting military efficiency*, (34) 1850
  tract, foreign bodies in, (45) 1666, (138) 2200
  tract, obstruction of upper, (46) 622
  *tract, surgery of esophagus and upper*, (104) 69
REST and exercise for tuberculous and predisposed children at school, (89) 2016
  and repair in lung tuberculosis, *466
  *and simple diet, prolonged, in nephritis*, (34) 2014
RESUSCITATION, (65) 435
  of apparently drowned, methods of, (10) 619
  respirator an appliance for, by producing enforced artificial respiration, (66) 808
RETINA activity, impaired, causes and symptomatology of, (30) 1937
  detachment, (24) 807
  detachment improved by simple sclerectomy, (55) 1077
  *detachment, operative treatment*, (36) 2325
  images, outward projection of, its bearing on shooting, (15) 225
  macular, anomaly of, (93) 1489
  melanotic sarcoma of chorioid with apparent secondary involvement of, (25) 807
  tuberculosis, some forms of, (2) 2189
RETINITIS, albuminuric, (103) 1846
  *albuminuric, of pregnancy*, (145) 368
RETRACTOR for abdominal contents during peritoneal closure, new, *2066
  perineal, self-retaining, new, (101) 1072
  perineorrhaphy, (98) 2016
  self-retaining, for use in perineorrhaphy, (122) 513
  self-retaining, small, for superficial dissections, (73) 1573
REVOLUTIONARY WAR, surgery of, (65) 711
RHEUMATISM, (99) 1415
  acute, (44) 2018
  acute articular, (49) 812
  acute articular, and arterial lesions (14) 2323
  acute articular, intravenous treatment, (64) 1845
  acute articular, recurring, rheumatic nephritis in, (54) 371
  articular, in soldiers, (88) 717
  bacteriology of, evidence in favor of causal relationship of streptococci, (28) 65
  chronic, genito-urinary surgery of arthritis deformans and allied varieties of, cure through (63) 1663
  *chronic, lesions in thyroid with*, (74) 1667
  gonorrheal, massage in acute and subacute stage of, (80) 435
  gout and rheumatoid arthritis, (6) 712
  in children, pathology of, heart in, 2269—ab
  Kuhne's remedy, 1315—P
RHEUMATISM, Lemmon's cure, 702—P
  mesothorium in gout and, (68) 716
  muscular, and fibrositis, (12) 1664
  phylacogen in chorea, (21) 1403
  *polyneuritis due to*, (110) 315
  salicylate in acute, scope of, (8) 309, (22) 713
RHINITIS: See also Colds
RHINITIS, acute, anaerobic organism *associated with*, (34) 1404
  atrophic, doriform in, (39) 311
  atrophic, etiologic and histologic aspects, (69) 223
  atrophic, treatment, (62) 1325, (58) 1934
  atrophic, with ozena, etiology and surgical treatment, (8) 1323 (11) 1487
RHINOLARYNGOLOGY in Great Britain, history of, (24) 901
RHINOLITHS, (67) 813
RHINOSCLEROMA, (11) 1490
RHINOPLASTY, early (81) 1749
RHODE ISLAND *medical news*, 207, 1547
  state board July report, 887
  state board October report 1925
RHUS poisoning, skin eruption due to, (3) 64
RHYTHM in vital phenomena, (64) 1851
RIB, excision of, in brachial pressure neuritis due to normal first thoracic rib, (27) 1936
  rupture of lung without rupture of, (178) 1499
  typhoid, treatment, (63) 1749
RICE, beriberiform polyneuritis produced in fowls with substances other than, (113) 712
  bran, nicotinic acid in, (25) 61
  plant, growth of, influence of salts common in alkali soils on, (58) 2015
  polishings, beriberi-preventing substances or vitamines contained in, (106) 1935
  polyneuritis gallinarum cured by intramuscular injection of substance isolated from, (16) 1843
  which prevents beriberi, character of, and manner in which it is milled, (15) 895
RICHARDS, Harriet M., balm of figs, 1312—P
RICHET, Prof. Charles, recipient of Nobel prize, 1915
RICHTER operation for atresia of esophagus, congenital, (106) 1846
RICIN intoxication in guinea-pig, (67) 439
RICKETS: See Rachitis

  erosions of, and general pathology, (88) 153
  eye in relation to, (81) 1664
  false, set of, removed from esophagus after incising neck, without opening esophagus, (97) 313
  loose, due to inflammatory degeneration of gums and alveolar process, treatment, *2232
  of school children in Germany, care of, (164) 147
  radio-active substances in morbid conditions in mouth and, (79) 228
  scraping and resection of tip of, without disturbing teeth above, (125) 155
  sepsis after extraction of, fatal, (104) 630
TEETHING, chronology of, (70) 1753
  does it ever produce morbid symptoms? (7) 618
  in children, (141) 146
TELECARDIOGRAPHY, (115) 2111
TELEPHONE and nerves, 204—E
  girls, neuroses among, nine cases, (165) 1499
TELEROENTGENOGRAPHY and orthodiagraphy of heart, (110) 1003
TEMPERANCE campaign in Argentina, (145) 524
TEMPERATURE and humidity in hospitals, 1541—E
  atmospheric, influence on spread of pneumonic plague, (111) 1935
  axilla and rectum, after long march, comparison of, (82) 905
  body, pharmacology of, (5) 1407
  body, share of nervous system in regulation of, (145) 2201
  centers, drugs applied directly to, (45) 2192
  during menstruation with lung tuberculosis, (102) 154
  in aged, (154) 1670
  in tissues during application of superheated air, diathermia or electrocoagulation, (57) 1938
  influence of fluid medium and, on survival of embryonic tissues in vitro, (55) 1571
  influence of water, carbonated and mud baths on, comparative, (73) 519
  influence on action of strychnin in frogs, (51) 993
  influence on Wassermann reaction, (145) 1418
  measurements, comparative, (151) 73
  of conjunctiva, *1124
  of diseased joints, (115) 1496
  of inspired air, influence of nose on, method of determining, (33) 1665
  premenstrual rise in, (65) 903
  reaction, polyvalent tuberculin and types of, new technic, (45) 2195
  rise in, in rectum, (96) 630
  variations, autogenous, local, cause of labyrinthine vertigo, (110) 145
TEMPORAL bones, examination of both, from 120 individuals regarding question of symmetry in health and disease, (2) 142
TEMPOROSPHENOIDAL abscess originating in ear, operation, recovery, (23) 1324
  abscess with meningeal symptoms, *1209
TENDON, Achillis, in etiology of weak-foot, *2029
  conjoined, absence of, anatomy of inguinal region with special reference to, (178) 147
  fixation-operation for prevention of deformity in acute anterior poliomyelitis, (15) 1569
  patella, destroyed, heavy silk used to replace, 1929—ab
  sheaths, multiple symmetric affections of bursae and, (90) 1333
  sheaths, sarcomas of, (37) 516
  sheaths, tuberculosis of lymph-nodes, muscle and, (71) 67
  sheaths, tumors in, (77) 629
  transplantation of, (40) 1410, (77) 1413
TENEMENT-HOUSE act requiring certificates of health department, validity of, 1927—Ml
TENNESSEE medical news, 207, 354, 693, 1547
TENON'S capsule, fat implantation in, (94) 1489
TERATA, formation of, (23) 305
TERATOMA, axillary, (109) 1935
  ovary, (9) 894
  removed from sacrum, (93) 1415
TERMINOLOGY of medicine and its original sources, (16) 2189
TEST: See also Reaction
TEST, acetic acid, dilute, to differentiate effusions and transudates, (163) 2202
  albumin, (89) 630
  albumin in sputum in diagnosis of tuberculosis, (115) 719, (35) 810
  albumin in sputum not reliable for early diagnosis of tuberculosis, (140) 154, (106) 1668, (18) 1855
  albumin in urine, gravimetric, (168) 378
  albumin in urine, quantitative, simple, (77) 904
  Bass and Watkins, 2001
  Binet-Simon, in detection of feeble-minded applicant for enlistment, value of, (104) 436
  Binet-Simon, mental measurement of 400 juvenile delinquents by, (70) 435
  Binet-Simon, reveals feeble-minded, 980, (32) 1844
  biologic, for progressive paralysis, (148) 722
  biologic, shows absorption of sperma in female serum, (123) 1943
  blood, clinical and microchemical, improved, *1897
  blood-supply with gangrene of foot, (163) 446
  breakfast, oil, (124) 1757
  Burnam's, for formaldehyd, 2038—C
  cancer, reaction of Salomon and Saxl as, (10) 1402
  carbon monoxid in atmosphere, 1475
  cerebrospinal fluid, for cancer, biologic, (107) 1416
  cerebrospinal, Ross-Jones, 618
  chlorids in urine, quantitative estimation of, simplified, (12) 431
  cobra venom, in syphilis, (102) 145
  cock's comb, for activity of ergot preparations, *19
  color blindness, (192) 234, (24) 437, (123) 1749
  epinephrin in blood, (107) 69
  feeble-minded, new, two, (117) 1072
  for absorption of fat, simple, (73) 1000
  for adult imbeciles and six-year-old normals, (100) 2104
  functional, clinical, methods, (16) 1487
  Guignaut's, for bile pigments in feces, superiority of, (177) 1338
  heart functional, 1839—ab
  hema-uro-chrome, for cancer and sarcoma, (8) 59, (31) 1662
  Herman-Perutz, 2001
  human milk, (136) 232, (135) 317
  hyperchlorhydria, (169) 74
  indigotin color, for indican, (21) 142
  iodin-ether, for bile pigments in urine and blood, (133) 155
  iodin in urine, (56) 812, (99) 1749, (80) 1939
  kidney function, (128) 442, (128) 816, (60) 903
  kidney function, and phenolsulphonephthalein, (1) 803
  kidney function, hemorenal index as, (67) 629
  kidney function, in uremia, (12) 1660
  kidney function, indigocarmin used intravenously as, (179) 148
  kidney function, phenolsulphonephthalein, *184, (56) 1077, (65) 1331, (30) 1487
  kidney function, phenolsulphonephthalein, error in, important sources of, (58) 1412
  kidney function, phenolsulphonephthalein, in scarlet fever, *1368
  kidney function, significance of methods of, (18) 1487
  kidney function, urea content of blood as, (176) 1499
  kidney function, value and limitations of, *939

TEST, Kowarski's, for differential diagnosis of diabetes, (101) 1334, 1921, 2260
labyrinth function, value in diagnosis, (46) 1849
Lange's, of cerebrospinal fluid in congenital syphilis, *13, 1921
levulose, of liver function, importance of, (93) 1495
liver function and disease under experimental conditions, (45) 222, (18) 2190
liver function, clinical use of carbohydrates, (37) 2272
liver function, fibrinogen for, 2162—E
liver function, lactose tolerance as influenced by liver necrosis of chloroform poisoning, (38) 2272
liver function, lipase for, 2162—E
liver function, new, 2162—E
liver function, phenoltetrachlorphthalein as, value of, experimental and clinical study of, 2162—E, (17) 2190
liver injury, (19) 2190
lordosis, albuminuria induced by, as sign of tuberculosis, (227) 1672
meal, opaque, standard, for roentgenography, (3) 2274
meiostagmin, for cancer, technic for, (142) 2113
mental, in diagnosis of feeblemindedness in children, early, desirability of, *2294
neutral sulphur in urine, (135) 1005
ninhydrin, for peptone, 2313—C
nitrite destruction as, for determination of water pollution, (46) 511
nitrogen and ammonia-nitrogen in urine, clinical, *87
occult blood in gastro-intestinal tract, (37) 1577
ovary functioning, (135) 1757
Overbeck-Wright, of chlorids in blood, (11) 624
palmin, Ehrmann's, (84) 809
pancreas functioning, (120) 816, (68) 1939
perception of light and colors, (99) 1495
permeability of arteries in gangrene, (53) 1666
von Pirquet, simple method of applying, *27
Rideal-Walker, approved technic of, (7) 219
Rimini-Burnam, for formaldehyd in urine, 1832
seminal fluid, (162) 1006
sight, of board of trade, criticism of, (8) 2017
skin reaction to chemical stimulation, method of, (108) 1496
stomach functioning, improved technic, (120) 441
sugar in blood, Bang's method, (117) 1942
sugar in urine, quantitative and qualitative fermentation, (98) 1495
sugar in urine, various, (102) 2111
tube reactions of elements of blood, differential, (164) 2202
tuberculous nature of effusions, intradermal skin reaction in guinea-pigs as, (105) 315
uranil, for uric acid in blood, (96) 313
urates in blood-serum, technic for, (147) 73
urea in blood, new, (80) 1325
urine, for cancer, (76) 904
urochromogen in urine, (78) 1332
urochromogen, Weiss' permanganate, (169) 446
vision, on suspicion of malingering, (110) 1668
TESTICLES, bilateral disease of, azoospermia not necessary consequence of, (79) 717
cancer, (88) 68, (180) 1338
effect of tuberculosis of epididymis on prostate and, (42) 61
extract, action of, (50) 307
hemorrhagic infarct of, (92) 229
internal secretion of, (165) 233
transplantation of, *1869
tuberculosis in undescended, (61) 311
tumor of, following herniotomy, (48) 1410
tumors of, mixed, probable embryologic origin of, *2054
undescended, (34) 1662
TESTICLES, undescended, inflammation of, acute, (167) 2026
undescended, treatment, (143) 1005
TESTIMONY as to Roentgen-ray pictures without their production, not best evidence, 2267—Ml
*expert, proper subject for, 1397—Ml*
of persons injured in accidents, (156) 1337
TETANUS, 278—T, (48) 433
antitetanic serum and chloral in, (141) 2106
antitoxin, 568
antitoxin, administration and value of, 687—E
experimental, in guinea-pigs, cure of, (23) 2275
head, (88) 2021
immunity from, duration of, after injection of tetanus serum, 788
infant, newborn, recovery, (97) 1495
neonatorum, three cases, (63) 2273
non-traumatic, (68) 1413
phenol, subcutaneous injection, in, (129) 523
prophylaxis, (121) 1936
puerperal, (10) 148
quinin and, (111) 1574
serotherapy of, (90) 1853
toxin, passive immunity against, duration of, (125) 368
treatment, (38) 1404
treatment, rational, (4) 59, (13) 304
TETANY, 2067—T
calcium bromid in laryngospasm and, (155) 157
cataract in, (168) 158
experimental studies in, (18) 2322
in children, pathogenesis of, (78) 228
infants, glucuronic acid in, excessive elimination of, (72) 1413
infants, newborn, (100) 314
rachitis with osteomalacia and, tardy, (60) 1493
stomach, in adult, (11) 2106
with abdomen disease bad sign, (153) 2025
with perforation peritonitis, (84) 905
TETRAGENUS septicemia, (31) 226
TEXAS, evicting medical quacks from, 504—P
Guinan obesity cure, 2173—P
medical news, 130, 355, 421, 974, 1728, 1993 2252
THEATER in service of hygiene, 135
THEOBROMIN sodium salicylate, intravenous injections of, (100) 1749
THERAPEUTICS, anarchy in, conditions tending to produce, commercialism, credulity and criticism, (49) 1405
guiding principle in, (39) 437
hasty generalization in, 603—T
ions as factors in climate and, (111) 1080
need of re-organization in methods and teaching of, (36) 897
teaching of, *525
THERMOCAUTERY to precede filling of bone cavities, (182) 1338
THERMOMETRY, nose, method of determining influence of nose on temperature of inspired air, (33) 1665
THERMOPRECIPITIN reaction, (85) 520, (176) 1672
THIALION, 213
THIERSCH flaps, improved technic for, (60) 1077
graft versus tampon in operation on ear for hearing, *1211
grafts, thickening of, excessive, due to component of scarlet red, (12) 1746
THIGH, amputation of, in patient of 108, recovery, (116) 367
amputation of, intra-uterine, with closure of urethra and rectum, (123) 631
amputation of leg or, autoplastic operations to cover stump subsequent to, *1792
THIOSINAMIN, cicatrix treated by multiple incision and, new method, (6) 2017
influence on urethra strictures, (72) 153
THIRIAR and Motais, death of professors, 290
THOMPSON, Robert, diary of, of Dublin, 2265—ab
THOMSEN'S DISEASE: See Myotonia Congenita
THORACIC duct in chick, histogenesis and morphogenesis of, development of blood-cells and their passage to blood-stream via thoracic duct, (1) 1323
lymph-nodes, primary infection with tubercle bacilli with special reference to, (36) 1324
THORACOCENTESIS, technic for, (163) 1006
THORACOPLASTICS and artificial pneumothorax in lung tuberculosis, (90) 1079
THORAX, artificial respiration during operations in, (42) 2277
closing pleural cavity after operations inside, technic for, (122) 1417
contamination of, and its contained lymph-nodes follows infection of peritoneal cavity, (20) 625
crushing with stasis cyanosis, (94) 1667
development and rachitis, (101) 718
empyema, bilateral, rib resection in, successive, (34) 1570
endoscopic methods as applied to, recent progress of, (49) 622
gunshot and stab wounds involving, (57) 715, (42) 811
gunshot wounds of, treatment, (54) 144
infection, experimental research on, (51) 715
movements of two halves of, in disease, (113) 1574
movements of walls of, during respiration, (125) 2199
roentgenoscopy of diseases of, (74) 1488, (115) 1574
roentgenoscopy of, in tuberculous meningitis, (30) 1570
sarcoma of, (13) 708
sounding-board as aid in diagnosis of disease of, (44) 622
surgery, 801—ab
surgery, rational pneumopexy in, (114) 1334
vertebrae, deformity in lower, frequent, (154) 1336
whitish streaks on skin of, from stretching, lineae albicantes, seven cases, (51) 371
wound in, closure under differential pressure, partial pneumothorax left after, (115) 1855
THORIUM, action of asbestos on radium and, in solutions of their salts, (7) 2274
THORIUM X, action on respiratory metabolism, (211) 1672
affinity of, for organs, (143) 232
and mesothorium in dermatology, (83) 2281
biologic action of, (141) 2201
biologic research on, (144) 232
experiences with, (105) 1854
in disease of blood, (129) 1418
in experimental cancer, local, (145) 72
in internal diseases, (168) 1671
in leukemia, disappointing experiences with, (82) 1853
intoxication, epinephrin content of adrenals in, (142) 2201
toxicity of, 1736
THREADWORMS: See Oxyuris Vermicularis
THRESHOLD levulose test of functional capacity of liver, (115) 1942
THROAT and ear clinics, British, historically considered, (28, 29) 901
cancer in mouth or, lymph-nodes in neck removed in operating for, technic, (43) 370
ether anesthesia in operations on nose and, (32) 1491
hemorrhage in operations on, (38) 1577
[illegible] disturbances of, (27) 516
[illegible] of nose and, (6) 112
sore, membranous, (75) 1749
sore, streptococcus, epidemic, symptoms, origin and transmission, *723
syphilis of nose and, arsenical compounds for, (21) 625
tuberculosis of nose, larynx and, electricity in, (105) 1750
THROAT, ulcerated, acid-fast bacillus from, stained by Neisser's method it resembles Klebs-Loeffler bacillus in its morphology, (1) 1329
THROMBOPHLEBITIS, puerperal, management of, (107) 1489
THROMBOSIS, (14) 2012
and embolism, 1839—ab
and embolism following operation and labor, (128) 2104
and embolism of superior mesentery artery, (13) 1746
and occlusion of lymphatics, (74) 2016
antemortem, in right heart and pulmonary arteries as cause of death in lobar pneumonia, (21) 1330
blood platelets in, (103) 815
cerebellar arteries, (159) 318
embolism and gangrene, treatment, (117) 2023
from slight overexertion of arm, two cases, (83) 1667
in measles, (84) 1333
lateral sinus, five cases, (58) 2103
mesenteric artery, (73) 307, (59) 999
otitic sinus, ligation of jugular vein in operative treatment of, (147) 1669
pelvis, of septic origin, surgical treatment, (136) 1327
pregnancy, physiologic, alleged, of vessels at site of placenta in uterus, (135) 376
septic, of both ophthalmic veins and cavernous sinuses, (92) 435
sinus, following necrosis of periosteal graft, (24) 1324
sinus, lateral, five cases, (58) 2103
splenic and portal veins, (94) 1003
traumatic, (50) 2278
traumatic, in axillary and subclavian veins, (128) 71
traumatic, of inferior vena cava in relation to life insurance, (139) 443
vena cava, cancer of kidney with, (77) 153
venous, with heart disease, (120) 2023
THROMBUS, pedunculated, in vagina in two pregnant women, (65) 2019
THUCYDIDES' plague probably exanthematous typhus, (91) 1078
THUMB, dislocation of, (61) 1753
THYMECTOMY, experimental, influence on growth, (64) 813
THYMIC-LYMPHATIC constitution and shape of epiglottis, (126) 1757
THYMUS: See also Goiter; Status Lymphaticus
THYMUS, abnormal, serodiagnosis of, is practicable, (79) 814
adrenal secretion in relation to, (143) 2024
and other ductless glands, (45) 144
and thyroid in their reciprocal relation to exophthalmic goiter, (88) 2197
cancer of, in man of 50, (169) 722
effect on organism, (142) 2024
gland in region of, previously undescribed, with internal secretion, (173) 234
hypertrophied, (171) 158
hypertrophied, operative treatment, (97) 1581
mammalian, regenerating capacity of, (92) 1495
pathology of, (141) 2024
physiology and pathology of, (98) 1334
roentgenotherapy of enlarged, (46) 144, 1841—ab
self-digestion of, (33) 433
thyroid and lymphatic system, reciprocal relations between, (76) 1579
tissue, Abderhalden biologic test for, (90) 1580
tracheal obstruction due to, (33) 1571
transverse myelitis secondary to cancerous degeneration of persisting, (122) 1855
THYREOTOXICOSIS and intestine intoxication, (122) 1574
THYROID: See also Goiter; Parathyroid
THYROID, (100) 154, (27) 1074
Abderhalden's test in disease of, (142) 1758

THYROID, abscess in, with pure cultures of typhoid bacilli 21 years after typhoid and followed by acute exophthalmic goiter, (61) 519
  and parathyroid glands of cows, 295
  and parathyroid problem, (87) 307
  and thymus in their reciprocal relation to exophthalmic goiter, (88) 2197
  artery, exophthalmic goiter cured by ligating one superior, (42) 1488
  cancer of, its extension to lungs by blood-vessels, (16) 363
  colloid, variations in, in conditions of hyper- and hypothyroidism, (28) 896
  concretions in, (99) 522
  cyst, congenital, in child aged 1 year, producing death by asphyxiation, (4) 2270
  disease, (134) 156
  diseases from surgeon's standpoint, (26) 2190
  excision of, (29) 2194
  excision of both lobes of, for cure of exophthalmic goiter, (10) 708
  extract in epilepsy, etiology, 137—ab
  extract in nephritis as preliminary to operation, *380
  extract in pregnancy, (35) 143
  extract in scarlet fever, (132) 1855
  extract, therapeutic use of salvarsan and, (89) 1406
  functioning, defective, operative treatment, (234) 1673
  in exophthalmic goiter, pathology of, (5) 2270
  influence on pregnancy and lactation, (148) 1328
  lesions with chronic rheumatism, (74) 1667
  pathologic changes in, in cretinistic variety of chondrodystrophia fetalis, (7) 432
  pathologic, treatment, (113) 2017
  pathology of parathyroids, hypophysis cerebri and, and their reciprocal action, (50) 1851
  radium rays in hypersecretion of, (28) 1575
  surgery of, *10
  thymus and lymphatic system, reciprocal relations between, (76) 1579
  tuberculosis of, (43) 517
THYROIDECTOMY, blood after, behavior of, (81) 717
  hemorrhage in, methods of controlling, (137) 2105
THYROIDITIS, acute, as complication of acute tonsillitis, (2) 803
THYROTOMY, cancer of larynx with operation by, subsequent hemilaryngectomy, (76) 307
TIBIA, fat implant to fill cavity in, (149) 1083
  pseudarthrosis of, operative correction, (83) 313
  transplantation of portion of, to spine for Pott's disease, (42) 627
  transplanting fibula to substitute shaft of, (72) 1579
  tuberculosis in shaft of, primary, resection, (133) 2113
TICK bite followed by wide-spread transitory muscle paralysis, (6) 64
  Persian miana bug as host of spirochetes, (25) 1409
TINEA cruris and cultivation of causal fungus, (4) 2321
TINNITUS, mesothorium and radium in deafness and, (169) 1671
  persistent, intracranial division of auditory nerve for, *327
TISSUES, action of, on hexoses, (31) 433
  action of leukocytes and other, on -dl- alanin, (78) 1325
  alcohol in, 1383—E
  amino acid absorbed from blood by, (55) 2015
  amino acid content of, effects of fasting and feeding on, (57) 2015
  amino nitrogen in, determination of, (54) 2015
  autodigestion of, antipepsin in blood prevents, (118) 719
  autolysates of embryonal, fetal and cancer, in cancer, evolution of basal theory, (140) 2113
  autolyzed, cultivation of amebas in pure culture on, (47) 992
  cells, living, and spirochaeta pallida in vitro, *1810
TISSUES, changes, pathologic, new indicator of, 1720—E
  changes, pathologic, paramecium as indicator of, 1921
  changes, under roentgenotherapy, (106) 154, (72) 228
  connective, growth of, mechanism of, (50) 993
  conversion of carbohydrates into lactic acid in, 1538—E
  depressor substance of dog's urine and nature of, (53) 898
  embryonal, research on, (164) 446
  flap, obliteration of mastoid excavation by implantation of, taken from temporal muscle, (90) 63
  growth, cinematograph adapted to study of embryology and, *401
  growth, in acid media, (32) 710
  increased blood-pressure a condition of effective working power through better oxygenation of, 874—E
  juices for eye, pathologic importance of, (80) 905
  living outside organism, (61) 66, (86) 313
  nose, intranasal transplantation of, attempt at, (6) 1323
  of adult frog, culture in vitro of some, (31) 64
  b-oxybutyric acid in blood and, determination of, (62) 2015
  pathologic, side-by-side examination of, and normal controls, advantages of, *1958
  process of digestion illustrated by action of stains on living, (31) 437
  regeneration, spontaneous, to close defects favored by position in which parts are held, (67) 1000
  spaces, transport of particles from, 1461—E
  stain for blood and, improved, (61) 2278
  temperature in, during application of superheated air, diathermia or electrocoagulation, (57) 1938
  (22) 364
TOBACCO, amblyopia, toxic, due to, (22) 364
  amnesias due to, *2297
TOE, big, reflex movements of, (135) 1418
  dislocation of finger or, compound, three cases, (150) 910
  dislocation of proximal phalanx of great, *2063
  drum-stick fingers and, in young man with lung tuberculosis, (142) 1944
  transplantation of phalanx from, into left ring finger, (77) 1078
TOFT, Mary, famous case of, pretended rabbit breeder of Godalming, (10) 509, (13) 895
TOMASCZEWSKI and Foster, demonstration of spirochaeta pallida in brain substance, *866
TONGUE, geographical, (150) 1498
  gumma of, salvarsan therapy in malignant syphilis praecox, syphilid of palms and, results, (74) 898
  operations on, infiltration of lingual nerve for, (119) 513
  swelling and ulceration of, (11) 309
TONSIL, abscess of, general sepsis following, (117) 1327
  and adenoid operations, (23) 432, (16) 991
  as avenues of infections and indications for removal, (97) 224
  diseased and enlarged, entire removal of, (80) 307
  diseased, physiology and treatment, (38) 2325
  enlarged, and adenoids, (18) 1490
  enucleation of, (42) 311
  enucleation of, and removal of adenoids, method of, (3) 1750
  faucial, and lung tuberculosis, what relation, if any, between? *113
  faucial, removal of, simplified technic for, (63) 994
  function of, (9) 142
  gangrene of, (118) 712
  glycolytic action of, (172) 1499
  hemorrhage from, and tonsillectomy, (92) 2194
  in relation to general diseases, (96) 224
  knife, tonsillectomies with special, 800 cases, (115) 1749
  lingual, diseases of, (48) 62, (102) 1846
TONSIL, offending, (24) 432
  operation, (110) 2016
  palatine, anatomy and comparative anatomy of, its rôle in economy of man, (13) 1490
  phlegmon of, (21) 1324
  plasma cells, significance of, *345
  removal of, complications of operation for, (70) 223
  removal of, indications for, (76) 63
  surgical anatomy of region of, (124) 1327
  syphilitic lesion of, primary, and Vincent's angina, differential diagnosis, (71) 223
  toxicity of human, (32) 1403
  treatment, conservative, (114) 718
  vestigial respiratory organ, (85) 1749
TONSILLECTOMY and tonsillar hemorrhage, (92) 2194
  and tonsillotomy, indications for and relative values of, (20) 1487
  at Massachusetts General Hospital, results after operation three or four years, (13) 1323
  bloodless practically, (29) 2323
  difficulties of, and how to deal with them, (38) 370
  in children, (114) 1942
  or tonsillotomy? (126) 155
  question, (74) 373
  Sluder method, *1243
  technic of, *1231, (87) 1853
  under local anesthesia, operation, new, results, *1227
  with special tonsil knife, 800 cases, (115) 1749
TONSILLITIS, acute, thyroiditis as complication of, acute, (2) 803
  following use of staphylococcus spray, *393
  pharyngeal, acute, (71) 623
  transient glycosuria in acute, (121) 816
TONSILLOTOMY or tonsillectomy? (126) 155, (20) 1487
TOOTH powder nostrum, calox, 978—P
TORONTO General Hospital, opening of new, 499
TORPOR recti, (53) 307
TORTICOLLIS, congenital, hereditary, (1) 996
TOURNIQUET, simple, *965, *2066
TOUCH, sense of, (114) 1081
TOXEMIAS, prostate and seminal vesicles in general, rôle of, *822
TOXINS, streptothrix, (131) 523
  thermostabile, in urethra and bladder infections, (131) 146
TRABECULAE in spleen in rachitis, increase of, (121) 1334
TRACHEA, endoscopic methods as applied to, recent progress of, (49) 622
  foreign body in, in infant, extraction of, (132) 523
  foreign body in larynx and, removed by aid of suspension laryngoscope, (75) 223
  obstruction due to thymus, (33) 1571
  paper clip in, successful removal, (131) 1936
  phlegmon starting as peritonsillar abscess and extending downward as far as second ring of, (62) 994
  stenosis of larynx and, chronic, (64) 994
TRACHEOTOMY in diphtheria of larynx, twenty cases, results, (65) 994
  laryngectomy subsequent to, for epithelioma of larynx, (29) 810
TRACHOMA, (98) 623, (144) 1418, (72) 2103
  among Indians, *1113, (122) 2017
  and epitheliosis desquamativa, (5) 436
  bodies, cultivation of, experiments on, (50) 1933
  in Kentucky, *1116
  in Palestine, (101) 1495
  iodic acid in, (42) 1070
  legislation needed in regard to control of, (125) 899
  prevalence and control among immigrants, *1110
  regulations in different states, 979
  tarsus in, (45) 2015
  treatment, (105) 2198
  treatment from surgical standpoint, (19) 432
TRADE-MARKS, new regulations in regard to, (143) 1497
TRANSFUSION, accidents in, prevention by preliminary blood examination, *2138
  blood, direct, technic, indications and advantages of, (175) 722
  blood, from pregnant woman, uncontrollable vomiting of pregnancy arrested by direct, (90) 439
  blood, in extra-uterine pregnancy, (183) 147
  blood, new and simple method, *117
  blood, normal, fresh, method for, (94) 889
  by glass cylinders, *1628, (12) 2189
  dangers of, and means to avoid them, (58) 2278
  therapeutic possibilities of, *298
TRANSILLUMINATION in diagnosis of chronic internal hydrocephalus, (115) 2022
TRANSMISSION of verruca by phlebotomus, *1717
  pellagra, from man to monkey, (95) 1935
TRANSPLANTATION: See also Grafting
TRANSPLANTATION, bone, (91) 223
  bone and joint, (41) 1410, (87) 1494
  bone, for flail joint produced by inflammatory destruction of joint, (95) 2016
  bone, to close defects in skull where large areas have been destroyed by trauma or disease, new method, (25) 1747
  femur, (133) 818
  fibula to substitute shaft of tibia, (72) 1579
  hair-growing skin, (155) 1499
  ileum, portion of, for formation of artificial vagina, Baldwin's operation, (48) 1750
  intestine, after extensive excision of sigmoid, experimental, *544
  intranasal, of nose tissues, attempts at, (6) 1323
  kidney, (48) 1938
  kidneys, functioning of, (135) 156
  mucosa from bladder, stomach, etc., experimental, (43) 1410
  muscle, cure of ischemic contracture by, (81) 629
  nerve, exposure of brachial plexus with, *15
  nerve, in paralysis of face, (109) 224
  of organs, 55, (119) 1668
  periosteum, experimental, (91) 68
  phalanx from toe into left ring finger, (77) 1078
  rectus, for deficiency of internal oblique muscle in inguinal hernia, (15) 1746
  tendons, (40) 1410, (77) 1413
  testicle, *1869
  tibia, portion of, to spine for Pott's disease, (42) 627
  tumors, in animals with spontaneously developed tumors, (143) 1327
TRANSPOSITION, viscera, complete, (118) 146
TRANSUDATES, dilute acetic acid test to differentiate effusions and, (163) 2202
  sugar in exudates and, (116) 2198
TRAP, maggot, new weapon in warfare against typhoid fly, (15) 510
TRAPEZIUM, dislocation of joint between metacarpal bone and, in thumb, (61) 1753
TRAUMA, abscess in brain due to, (44) 1410
  and bone tuberculosis, (117) 63
  birth, 2097—ab
  birth, hematoma from, subdural, puncture of fontanel for, (143) 317
  birth, in epilepsy and insanity, 2096—ab
  birth, intracranial, 2096—ab
  birth, surgical treatment, 2096—ab
  cerebrospinal meningitis following, in adult, (101) 1581
  Erb's paralysis due to, in adult, (27) 2101
  hysteria due to, (37) 1662
  in aggravation of preexisting disease, (16) 1073
  neurasthenia due to, and malingering, (27) 2323

melanic, throughout gastro-intestinal tract, generalization of, (39) 370
metastases, production and growth of, factors in, (28) 621
mouse, influence of anesthetics on, (221) 1672
*nasal septum, (61) 994*
nerve tissue, simulating spina bifida, (36) 516
omentum, with twist of pedicle, giving symptoms of acute appendicitis, (55) 512
ovary, and pregnancy, (72) (311)
ovary, cancer of pelvic colon and appendicitis necessitating repeated abdominal section, (4) 1490
ovary, complicating pregnancy and labor, (2) 1485
ovary, seven-pound, developed in nine days, (19) 2101
*pararenal* (143) 2113
parotid gland, (102) 2282
pineal gland, (190) 1672
producing agent, resistance to, as distinct from resistance to implanted tumor cells, (57) 1571
proper and hyperblastosis, (24) 2190
purins and purin metabolism of some, of domestic animals, (45) 1932
radiotherapy of, (88) 1078, (106) 1756
radium in malignant, (16) 149 (27) 998, (44) 1492
rat, intravascular implantation of, (66) 1071
*roentgenotherapy* of benign and malignant, (31) 1330 2098—ab
sacrococcygeal, (35) 1069
sacrum, *congenital, (93) 1415*
serodiagnosis for differentiation of, (114) 230
simulating branchiomas, (68) 999
skin, benign, cancerous changes in, (5) 59
spinal cord, (70) 1852 (78) 1667
spinal cord, diagnosis of, local, (200) 1760
spinal cord, surgery of, from neurologic viewpoint, (167) 147
spinal, localization of, methods with reference to medical and surgical treatment, (77) 223
spine, near atlas, paralysis of trunk from, total, apparently normal labor with, (167) 74
**TUMORS**, spine, with scoliosis, operation, (31) 226
stomach, tuberculous, (119) 1855
stomach wall, diagnosis, (95) 1755
subcutaneous, hard, (187) 1672
subglottic, two cases, (32) 1665
submaxillary gland, solid, (77) 2193
tendon sheaths, (77) 629
testicle, following herniotomy, (48) 1410
testicle, mixed, probable embryologic origin of, *2054
tissue, human, cultivation of, outside *organism, (154) 73*
transmissible, and nutrition, 1378—E
transmissible, of rats and mice in relation to diets and castration, (45) 433
transmutation of, 1565—ab
transplantation of, in animals with *spontaneously* developed tumors, (143) 1327
urinary bladder, benign and malignant, D'Arsonval current in, through operating cystoscope, value of, (136) 2104
uterus, cervical stump of, malignant, development after supra*vaginal hysterectomy, (34) 1069*
uterus, cystic, congenital, (64) 439
uterus, histologic diagnosis, (76) *1078*
ventral, of sacrum, (112) 1489
wound-infection curing, (155) 1944
**TURBINECTOMY** in hemophiliac, epistaxis following, human blood-serum injected in, (8) 142
**TURKISH** hospitals, two, (103) 899
**TURPENTINE**, intoxication from inhalation of, (127) 523
poisoning producing scarlatinoid *rash, *412*
tampon for puerperal endometritis, (77) 1494
**TWINS**, cancer of uterus cervix containing, advanced, vaginal hysterectomy for, (34) 1575
syphilitic, malformations in pair of, identical, (28) 1409
**TYMPANUM**, topography of, (60) 365
**TYPEWRITERS**, psychophysiologic signs of superior skill among, 695
**TYPHOID**, (95) 224, 1457—T, 1536—T, (71) 2273
abscess in lung during, operative cure, *(170) 74*
agglutinins in tissues cultivated outside organism, specific, production of, (161) 158
anaerobes in, (50) 999
*and filtered* water, relations between, shown in two years' service of Wilmington filters, (21) 1069
autoreinfection with, (71) 1852
bacilli, abscess in thyroid with pure cultures of, 21 years after typhoid and followed by acute exophthalmic goiter, (61) 519
bacilli carrier, perineal suppuration in, (85) 905
bacilli in feces, persistence of, after recovery from typhoid, (146) 910
bacilli, isolation of, from milk causing typhoid outbreak, *1024
bacilli, living, in vaccination contra-indicated by danger of making typhoid carriers, 1814—E
bacillus, otitis media, suppurative, acute, due to, (49) 144
bulbar paralysis in, (33) 143
campaign against, in Southwestern Germany, 501
carriers, (25) 306 (44) 2107
carriers, conditions found in necropsy, 202—E
carriers, contamination of milk by, 1905—E
*colon* intermediate group of bacilli with special reference to complement fixation reactions, (39) *1403*
complications and later day treatment of same, (51) 144, 1630—T
death rate of Memphis, 359
diagnosis, (88) 898
diagnosis on admission to hospital, (23) 709
diet, gelatin and olive oil in liberal (70) 512
epidemic, (3) 1329
epidemic, and paratyphoid, (17) 516
epidemic, Quincy, Ill., (37) 511
**TYPHOID** epidemic, typhoid vaccine in, (6) 59
fly-borne, 841—ab
fly-borne, its control in Jacksonville, (119) 224
from uncooked vegetables, (102) 712
gall-bladder symptoms in, (116) 316
gangrene and cholera, (94) 2282
hematuria due to hexamethylenamin given in, (74) 1332
*hemiplegia* complicating influenza and, three cases, (102) 1581
immunized milk as prophylactic and cure for tuberculosis and, (119) 1574
immunotherapy, principles and practice of, (144) 146
in Australasia, 352—E, (2) 436
in Canal Zone, *1893
in child complicated by stenosis of larynx, (78) 520
in Cleveland in 1912, (38) 1662
in Halifax, 2253
in regiment traced to old bacillus carrier, (115) 375
in Yakima Valley, year's work against, results, (18) 1069
*infantile anemia*, severe, cause of, (151) 1498
infection, atypical, (7) 1660
infection of appendix, (87) 63
intercurrent, or typhoid vaccination in chronic lymphatic leukemia, (98) 2282
intestine hemorrhage in, (34) *2014*
investigation and control of, plea for more widespread interest in, (20) 1069
irrigation of lower intestine in, 214
leukemia *stimulating lesions of,* (52) 2326
municipal control of, (22) 1069
pathologic conditions following, *(74) 809*
percussion sign of, (46) 811
periostitis, chronic 1742—ab
prevention of, 782 893—ab
plus measles, (71) 1414
problem, practical phases of, (110) 712
prophylaxis and treatment, (78) 307
*prophylaxis* by injection of killed cultures, (116) 1749
recent literature on, (54) 1331
reduction in Australasia, (12) 148
rib, treatment, (63) 1749
*rural, in Manitoba, (19) 1069*
signs of, treatment, (34) 1330
transmission of, (120) 224
ulcer, perforative, operations for, successful, (5) 1490
unusual cases of, two, (14) 225
urea and nitrogenous bodies in blood in, (67) 311
*vaccination*, (72) 144, (145) 146, (24) 1408, (30) 1488, (51) 1662, (8) 2270 (22) 2324
vaccination, experimental research on, (97) 2282
vaccination in civil communities, value of, (94) 2016
vaccination in navy, 355
*vaccination, institutional, (23)* 1069
vaccination or intercurrent typhoid in chronic lymphatic leukemia, (98) 2282
vaccination, progress during 1912, *666
vaccination, prophylactic, and effect on menstruation, (19) 2012
vaccination wholesale, (65) 66
vaccine, 27 568, 869, 1297, 1900
vaccine *therapy* (6) 59, (90) 995, (95) 1326, 2255
watercress causing, 971—E
Widal's agglutination *reaction* as aid in prognosis in, (47) 2019
**TYPHUS** See also Brill's Disease
**TYPHUS** and small-pox in Bosnian refugees, (157) 73
*bacteriologic* findings in, (120) 375
exanthematous, (92) 2198
exanthematous, blood-findings in, *(106) 2198*
exanthematous, parasite of, (122) 2199
exanthematous, *serodiagnosis* of, (150) 722
exanthematous, Thucydides' plague probably, (91) 1078
sporadic case of, *1629
**TYROSIN** content of proteins, (57) *62*
preparation of, (34) 433

U

ULCERS, adhesive plaster as direct dressing for, its fulfilment of Bier and Wright principles, (33) 306
and cancers of intestinal tract, surgical treatment, (56) 512
cornea, methylene blue in treatment, (117) 2017
duodenum, (90) 68, (70) 228, (8) 713, (69) 994, 1177—ab, (98) 1415, (126) 1490, (101) 1756
duodenum, and bile tract infections, 2009—ab
duodenum, and chronic appendicitis, their association, (12) 142
duodenum, complications of, (90) 1664

incontinence and prolapse of vagina, (70) 311
incontinence, complete and incomplete, (119) 2104
incontinence in children, 2158—T
indican and indol in, relations between, (146) 1758
indican in, test for, (99) 1749, (156) 2202
indications from, in treatment of certain skin diseases, (74) 2103
indolacetic acid in, excretion of, (13) 431
influence of thermal douche massage on elements of, (104) 1003
iodin in, test for, (56) 812, (80) 1939, (94) 2197
liver insufficiency estimated from nitrogen partition of, (16) 2323
mercury in, in persons handling mercury, (175) 74
neutral sulphur in, in cancer, unreliability for diagnosis, (149) 1944
nitrogen, (58) 1077
nitrogen and ammonia-nitrogen in, clinical tests for estimation of total, *87
nitrogen compounds in, in fever, (138) 1005
URINE, non-dialysable constituents of, (81) 1580
of parathyroidectomized dogs, toxic bases in, (30) 433
of tuberculosis patients, urochromogen reaction in, (164) 1006
phosphates in, of bottle fed infants, (137) 232, (136) 317
reaction, ferric chlorid, and impending diabetic coma, (140) 1836
rectum as receptacle for, (56) 1666
residual, is enlarged prostate cause of? (59) 2019
residual, may interfere with action of local disinfectants, (62) 1666
retention, acute, with imperforate hymen in girl of 15, secondary fatal peritonitis, (142) 909
retention, Chetwood operation for, ultimate results, (68) 1488
sodium bromid and sodium chlorid in, determination of, 428
sugar in, fermentation test of, quantitative and qualitative, simple, (98) 1495
sugar in pentosuria, nature of, 1302—E
sugar in, tests for, various, (102) 2111
suphates of, feces and indicanuria, (63) 711
sulphur, neutral, in, test for, (135) 1005
sulphur test, Salomon-Saxl, for cancer, (10) 1402, (149) 1944, (141) 2113
test for cancer, (76) 904
toxicity of, with anaphylaxis, (180) 1759
tube-casts in, (93) 2197
urea in, determination of, (81) 1325
urea in, Marshall's method for estimation of, (115) 1581
urea, uric acid and purin bases in, azotometer for quantitative determination of, (137) 2024
urobilinogen reaction in, (116) 718, (78) 1332
UROBILIN and urobilinogen in body fluids, significance of, (75) 1001
reaction, formaldehyd interferes with, (78) 1413
UROBILINOGEN and urobilin in body fluids, significance of, (75) 1001
reaction in urine, (116) 718, (78) 1332
UROBILINOGENURIA in diagnosis, (127) 817, (201) 1672
UROCHROMOGEN reaction in urine of tuberculous, (164) 1006
Weiss' permanganate test for, (169) 446
UROLOGY and proctology, (94) 435
as science and course in medicine, (183) 1760
diagnosis, (96) 809
microscope as localizer of disease, (80) 366
mid-operative diagnosis in operations in, *174
serology and vaccine therapy in, 1730
UROTROPIN See Hexamethylenamin
URTICARIA and pruritus in hyperthyroidism, treatment for, 2261
calcium lactate in hay-fever and, 428
diet in, (170) 1338
purpura and angioneurotic edema of hands and feet in nursing infant, *18
UTA, verruga peruviana and oroya fever, *1713
UTAH medical news, 1467, 1822
state board January and April reports, 57
state board July report, 503
UTERINE muscle, nitrogen extractives in, (60) 1938
pelvic support, anatomy of, (68) 1934
UTERUS, action of emmenagogue oils on isolated, *105
adenocarcinoma of body of, and adenomyoma diffusum benignum, (14) 515
adenoma of cornua of, diffuse, (66) 2196
anteflexion of, defective function and sterility, treatment by glass or silver stems, (7) 1842
arteriosclerosis of, and uterine hemorrhage, (73) 68
aseptic means to introduce hand into, (111) 816
atrophy of, due to lactation, (66) 1331
UTERUS, Baldy-Webster operation for, end-results, suspension of, *1430
cancer, (49) 807
cancer, and American Society for Control of Cancer, (83) 2274
cancer, and fibroid tumors from clinical standpoint, 1323—ab, (11) 2101
cancer, another hypothesis as to cause and prevention, (110) 1489.
cancer, complete recovery from, (114) 440
cancer, curetting, exploratory, as diagnosis of, (122) 155, (38) 227
cancer, curetting, exploratory, for cure of, (109) 815
cancer, cystoscopy with, importance of, (19) 1850
cancer, daily paroxysms of pain as sign of, (157) 1006
cancer, early diagnosis, *1264, (87) 1664, (54) 2273
cancer, hysterectomy for, vaginal versus abdominal, (38) 2277
cancer, in Riga district, (92) 815
cancer, incipient, treatment, (132) 1004
cancer, inoperable, combined treatment, (101) 907
cancer, inoperable, ligation of internal iliac and ovarian arteries for, combined with curettage and cautery, (16) 624
cancer, morphology of, (74) 67
cancer of body of, clinical status, (73) 1078
cancer of cervix, (9) 619
cancer of cervix, cautery in radical treatment, (184) 147, (36) 2272
cancer of cervix, containing twins, vaginal hysterectomy for, (34) 1575
cancer of cervix, histology of, (84) 1754
cancer of cervix, palliative vaginal hysterectomy for, with recurrence after ten years, (46) 715
cancer of cervix, pulverized sugar as palliative dressing for, (180) 159
cancer of cervix, radical operation for, results, (35) 2107
cancer of cervix, retrogression of bladder changes under roentgenoscopy of, (153) 2201
cancer of cervix, theoretical and practical foundations of radical operation for, *1266
cancer of pregnant, (174) 1758
cancer of vagina and, inoperable, heat applied to inhibit and destroy, method, (119) 1489
cancer, operation for, (57) 1752
cancer, prophylaxis of, (166) 446, (46) 1577
cancer, radical laparotomy for, (177) 147
cancer, radium in, (109) 1855, (80) 2281
cancer, roentgenotherapy in, (138) 72
cancer, Wertheim operation for, (207) 1672
casts passed during menstruation, pathology of, (96) 307
cervix, lacerations of, (73) 366, 2089
cervix, lacerations of, cause of salpingitis, (8) 2101
cervix, non-dilated, obstetric forceps with, (157) 1499
contraction ring dystocia, (94). 1664
dysmenorrhea from imperfect development of, or malformation, (88) 1071
dystocia, secondary to mitral stenosis, (76) 512
elastic area in isthmus of, positive and early sign of uterine pregnancy, (6) 895
embedding in paraffin histologic sections of ovaries and, improved technic, (137) 1335
emptying of, in puerperal eclampsia, (5) 895, (101) 996
fibroids, (56) 1325
fibroids and pregnancy, (4) 1329
fibroids in which degeneration of tumor—perithelioma and necrobiosis—caused difficulty in diagnosis in, (35) 1665
fibroids, operation in, early, (8) 1847
fibroids, roentgenotherapy of, (20) 305, (25) 1750
UTERUS, fibromyoma, angiomatous, hemorrhages into atheroma of uterine ateries and, (25) 997
fibromyomas of lower uterus segment, (12) 2101
fibrosis of, nodular, diffuse, (23) 1330
foreign body in cervix, to prevent conception, removal of, *868
fractures of, multiple, intra uterine, case of, (78) 1934
gastrectasis following ventral fixation of, with long labor, (4) 2101
gravid, uncontrollable vomiting connected with retroversion of, cured by correction, (75) 1494
growths, new, rare, simple papilloma of corpus uterus, primary tubercle bacillus of cervix uterus, diffuse nodular fibrosis of uterus, (23) 1330
hemorrhage from, (126) 224, (98) 1574, (119) 2112
hemorrhage from, in newborn infants, (125) 1855, (164) 1945
hemorrhage from non-pregnant, *672
hemorrhage, optic atrophy due to, (18) 432, (84) 513
hemorrhage, pathoogy and treatment, (50) 65
hemorrhage, significance of, 989 ab
hemorrhage, tendency to, arrested by radium emanations (166) 74
hemorrhage, Wassermann reaction in diagnosis of, (11) 1847
hemorrhagic disease of, and myomas, efficacy of mesothorium radiotherapy in, (124) 155
hernia of, and both adnexae, (126) 2104
high straight position in, (132) 1334
inertia, (2) 1569
inertia, artificial labor in, under what conditions? (108) 1489
inertia, pituitary extract in, (4) 509
inertia, treatment, (122) 1489
infantile type of, with dysmenorrhea, (115) 1846
inversion of, (95) 307, (36) 1665
inversion of, postpuerperal, (5) 623
inversion of, puerperal, (85) 229
lactation atrophy of, 1320—ab, (2) 2101
lesions of cervix, diffentiating, diagnostic errors in, 1565—ab
leukoplakia of, (10) 894
lipoids in human, (124) 909
loop for pulling out, in vaginal operations, (151) 377
malignant tumor of cervical stump of, development after supravaginal hysterectomy, (34) 1069
malpositions of, best methods of dealing with, (6) 1847
massage of pregnant, (124) 522
measurement of, *746
mucosa, structure of, in health and disease, (34) 1410
muscle tissues and peritoneum, intimate relations between, (62) 151
myoma and cancer of, (71) 1934
myoma and myosarcomas of, (36) 1410
myoma, cervical, (110) 1574
myomas complicating pregnancy, (143) 444, (6) 1329
myomas of, etiology, (154) 1758
myomas of, hemorrhage in ovary in, (133) 1943
myomas of, roentgenotherapy of, (88) 1853
myomatous, torsion of, (112) 816
obliteration of, partial, and total occlusion of uterus cervix after puerperal sepsis, (4) 1843
os, dilatation of, instrumental, in eclampsia, advantages of, (136) 1944
papilloma of corpus, simple, (23) 1329
preventing peritonitis after operative treatment of rupture or perforation of, technic for, (75) 1078
prolapse, cystocele and rectocele, etiology, mechanism and behavior, (7) 1485
prolapse, Duhrssen-Watkins-Wertheim operation for, *1246
prolapse of rectum and, at age of 27, (20) 516
prolapse of, treatment, (88) 1326
prolapse of vagina and, total, Freund's operation for, (164) 1758

UTERUS prolapse, vagino-uterine, effective treatment, *1245
  prolapse with hypertrophy of cervix, operation for, (24) 997
  puerperal, disinfection of vulva during labor reduces germ content of, (59) 1938
  retained placenta due to implantation in sacculus or horn of, (37) 2107
  retroversion, (51) 65
  retroversion, by transplanting round ligaments, (28) 2276
  retroversion, raising pelvis for correction of, (187) 1760
  retroversion, strain removed from round ligaments while healing after correcting, (105) 307
  retroversion, treatment, (84) 629
  retroverted, new procedure for relief of, (113) 367
  rupture, after pituglandol, (114) 1003
  rupture, complete, (79) 1853
  rupture, during labor traced to gonorrhea, (132) 2112
  rupture, spontaneous, at eighth month of pregnancy, (38) 2107
  ruptured, literature and case reports of, (106) 513
  sarcoma of, (12) 1575
  sarcoma of, metastasis of lung secondary to, simulating pneumonia, (19) 1936
  sarcoma of wall of, (112) 909
  stenosis of cervix, new method of treatment, (60) 2273
  strip, action of emmenagogue oils on, (81) 898
  syndrome, (56) 808
  syphilis of adnexa and, unwritten chapter in gynecology, (96) 435
  tears in cervix of, suturing as prophylaxis of local cancer, importance of, (131) 1004
  tubercle bacillus of, primary, (23) 1330
  tuberculosis, (49) 1666
  tuberculosis, miliary, (113) 909
  tuberculosis of body of, literature on, 295
  tuberculous fetus in, of woman who died from tuberculosis, (54) 311
  tumors of, cystic, congenital, (64) 439
  tumors of, histologic diagnosis, (76) 1078
  unicornis, pregnancy in rudimentary cornu of, case with full term fetus, (110) 1846
  ventrofixation of, method of, combined with certain tubal sterilization by means of extra-abdominal development, (123) 513
UZARA, action of opium and, comparison, (86) 1853

V

VACATION, summer, classes in Vienna, 356
VACCINATION, abdominal pain, acute, and, (10) 1329
  alarming increase of non-vaccinated, 609
  and immunity, (8) 1329
  aseptic, iodin in, (14) 2017
  autumnal hay-fever, 212—C
  bovine, does small-pox protect against, 2089, 2314
  calf lymph for, in Sydney, bacteriology of, (12, 16) 899
  chicken-pox, (36) 2277 (58) 2326
  criticism of facts against, (79) 1406
  diphtheria, Behring's, (123) 70, (81) 2281
  hay-fever, with mixed cultures from nose in, *1806
  prevention by, (39) 711, (86) 809
  question, 422
  sensitized virus, in gonorrhea and complications, (46) 2108
  small-pox, and conscience, 778—E
  small-pox, duration of immunity following, *487
  small-pox, skin reaction after, (42) 364
  tuberculosis, von Ruck's method, results, (97) 63
  typhoid, (72) 144, (145) 146, (90) 995, (24) 1408, (50) 1488, (51) 1662, 2255, (8) 2270, (22) 2324
  typhoid, experimental research on, (97) 2282
  typhoid, in civil communities, value of, (94) 2016
  typhoid, in navy, 355
  typhoid, in typhoid epidemic, (6) 59
  typhoid, institutional, (23) 1069
  typhoid, or intercurrent typhoid in chronic lymphatic leukemia, (98) 2282
  typhoid, progress during 1912, *666
  typhoid, prophylactic, and effect on mentruation, (19) 2012
  typhoid, wholesale, (65) 66
  with sensitized virus against sheep-pox, (49) 2195
VACCINE, acne, 27, 568, 869, 1297, 1900
  acne bacillus from comedo for, practical method of growing, (28) 310
  and serums in Malta fever, prevention and treatment, (4) 1401
  and serums, uses and limitations of, (121) 1072
  antigonococcic, atoxic, 1825
  antirabic, 1377
  autogenous, in chronic joint affections, (26) 148
  autogenous, in pyorrhea alveolaris, 885
  autogenous, of a coliform organism for acute agchylostomiasis, (16) 1408
  bacillus coli, 27, 568, 869, 1297
  bacillus pyocyaneus, 27, 669
  bacterial, acne pustulosa, rational treatment with special reference to, (68) 1573
  bacterial, in acute septic conditions of mouth met with by dentist, (13) 2189
  bacterial, in erysipelas, *2049
  bacterial, in pustular acne and furunculosis, (51) 1844
  bacterial, mixed, in lung tuberculosis in children, clinical reports of ten cases, (85) 435
  Bordet-Gengou, bacillus of, 568, 771, 2158
  diphtheria, Behring's, (51) 1851
  federal control over manufacture of serums and, *659
  Friedlander, 1297, 1900
  gonococcus, 27, 568, 1297, 1900
  gonococcus, and glycerol extracts of gonococcus in diagnosis of gonorrheal infections, (44) 1070
  gonococcus, in gynecology, value of, from differential and therapeutic standpoint, (35) 1410
  in infectious disease, chronic and acute, 400 cases, results, (58) 438
  in paratyphoid bacillus infection, (11) 2274
  in pneumococcic affections, 1393
  irradiated, 782
  meningococcus, 27, 568
  mixed, 1297, 1900
  pneumococcus, 27, 568, 869, 1297, 1900
  sensitized, (178) 1672
  sensitized, in acute bacterial infection, (27) 310
  soluble, in tuberculosis, (34) 365
  standardizing, simple and accurate method of, (36) 807
  staphylococcus, 27, 568, 869, 1297, 1900
  streptococcus, 27, 568, 869, 1297, 1811
  tubercle bacillus, non-virulent, 979
  tuberculosis, another, 979
  typhoid, 27, 568, 869, 1297, 1900
  variola, as source in culture of vaccine lymph, (154) 377
VACCINE THERAPY, (75) 63, (121) 224, (20) 510, 990—ab, (67) 1749
  and serology in urology, 1730
  bronchitis and asthma, chronic, (27) 149
  cancer, (127) 231, (95) 2021
  catarrh, (75) 144
  for general practitioner, *845
  gonorrhea, (119) 1004, (159) 1006, (108) 1080, (57) 1578, (109) 1756, (99) 2111
  gonorrhea, and regulation by serodiagnosis, (30) 65
  gonorrhea complications, (86) .1002
  gonorrhea in women and girls, (141) 72
  gonorrhea vulvovaginitis, (22) 901
  in infectious diseases of urinary passages, (239) 1673
  of bacterial infections, modification of, (52) 1492
  of ozena, (125) 1943
  pneumonia, series of cases, (86) 223
  practical consideration of, (42) 2018
VACCINE THERAPY, pseudoleukemia, etiology of, *2122
  scientific basis for, *2116
  typhoid, (6) 59, (95) 1326
  whooping-cough, 209, (39) 714, 988—ab, (60) 1749
VACCINIA and vaccination, etiology of, (91) 2111
  and variola, (155) 147
  cultivation of virus of, (36) 1404
  virus of variola and, have they been obtained in pure culture? 2074—E
VACUUM drying, volatility of sulphuric acid when used in, (59) 897
  Vaedske method, modification of, for blood count, improved technic. (134) 2114
VAGINA, artificial, (89) 154
  artificial, formation by transplantation of portion of ileum, Baldwin's operation, (48) 1750
  cancer of uterus and, inoperable, heat applied to inhibit and destroy, method, (119) 1489
  cancer, primary, and leukoplakia, (122) 909
  douches, hot, abuse of, (64) 228
  examination in little girls, (116) 1855
  formation of, (38) 517
  germs of, and endogenous infection, (126) 631
  hernia, repair for, new method of, 140 cases, (79) 2103
  irrigation of, and hammock Sitz-bath, (76) 1494
  laceration of, non-obstetric, fatal, (137) 1083
  operations, loop for pulling out uterus in, (151) 377
  pedunculated thrombus in, in two pregnant women, (65) 2019
  prolapse of, and urine incontinence, (70) 311
  prolapse of uterus and, total, Freund's operation for, (164) 1758
  restoration of, (123) 442
  secretions, intrapartum, streptococci in, prognostic significance of, (121) 909
  surgery, inverted T-incision in, importance and value of, (114) 146
VAGINISM, causes and treatment, (178) 378
VAGINISMUS is merely a psychic reflex or phobia, (17) 631
VAGINITIS, membranous, acute, in pregnancy due to enterococcus, (74) 307
VAGITUS uterinus, (116) 1574
VAGOTOMY and seasickness, (82) 814, (123) 1082
  pupil sign of, (125) 1082
VAGOTONIA, clinical study, (18) 2012
VAGUS nerve, effect of morphin on mechanism of dog's heart after removal of one, (23) 2322
  nerve, heart-block from irritation of, (125) 1418
  nerve, predominant influence of left, on conduction between auricles and ventricles of heart in dog, (24) 2322
  nerves, roentgenoscopy of woman with stomach and both, resected, (53) 812
  nevi, cardiacus, nucleus, and three distinct types of nerve cells which innervate three different types of muscle, (4) 894
d-VALINE and d-alannine, separation of, (42) 1747
VALVE ileocecal, incompetency of, (105) 146
VARICELLA: See Chicken-Pox
VARICES and pregnancy, (101) 229
  invisible, incipient, means to detect, (90) 1667
  legs, spiral incision in, (118) 316
  operation for, with minute incisions, (126) 1004
  saphenofemoral anastomosis in, (55) 812
  spiral incision in leg ulcers or, (84) 2197
VARICOCELE, castration and operations for hydrocele and, without wounding scrotum, (96) 366
VARICOSE ulcer, feeding it with cheese, (89) 1071
  veins, (138) 1497
  veins, aqueous solution of iodin infusion in treating, 2266—ab
  veins as described by Haly Abbas, *1455
VARIOLA: See Small-Pox
VARIOLOID in Manila, (82) 712
VAS DEFERENS, anastomosis of ovarian tube or, new method of, *2157
  cysts from absence of, (172) 722
  effect of cutting, 2179
VASOCONSTRICTOR substance isolated from blood and adrenal cortex, *2136
VASOMOTOR disturbances, abdominal, circumscribed, electrotherapy of, (63) 152
  disturbances and. dread neuroses, (102) 1003
  phenomena as premonitory symptoms in rheumatoid arthritis, (12) 996
VASOSTOMY, *1867
  radiography of seminal ducts, (180) 147
VAUGHAN, Victor C., leadership of, 55—C
VEGETABLES, green, cooked, in acute chronic diarrheas, (14) 991
  uncooked, typhoid from, (102) 712
VEGETARIAN diet of Japanese monks, (63) 372
VEINS, axillary and subclavian, traumatic thrombosis in, (128) 71
  disease of female genitalia and, connection between, (65) 1412
  grafting for maintenance of direct arterial circulation, (26) 310
  ileocolic, ligation of, with mesenteric pyemia after appendicitis, advantages of, (79) 2196
  jugular, ligation of, in operative treatment of otitic sinus thrombosis, (147) 1669
  jugular, ligation of internal, and resection of pneumogastric, danger from, (46) 627
  ophthalmic, and cavernous sinuses, septic thrombosis of both, (92) 435
  portal, ligation of, experimental, its application to treatment of suppurative pylephlebitis, (169) 148
  portal, ligation of, temporary, (135) 1669
  pulmonary, anomaly of left, *1893
  pulmonary, stenosis of left, with paralysis of left recurrent nerve, (151) 2024
  response to epinephrin, (100) 712
  splenic and portal, thrombosis of, (94) 1002
  trunk, suture during laparotomy, (177) 1758
  varicose, (138) 1497
  varicose, aqueous solution of iodin infusion in treating, 2266—ab
  varicose, as described by Haly Abbas, *1455
VENA CAVA, cancer of kidney with thrombosis of, (77) 153
  inferior, ruptured, suture of, (124) 441
  inferior, traumatic thrombosis of, in relation to life insurance, (139) 443
